# Pesticide register

by G. L. Mack

Pesticide chemicals have proliferated enormously in the last 25 years. From a few inorganic chemical and botanical poisons, the industry has developed over 1,000 different chemical pesticides. Most of these are synthetic organic chemicals with confusing names and complex structures. The PESTICIDE REGISTER is intended to bridge the gap between trademarked, generic, and preferred names by indexing and cross referencing.

The preferred name is designated by a four digit number in the left hand column. These numbers are *not* consecutive, and are permanently assigned (initially in units of 10), so that additions or deletions can be made without renumbering. Left column numbers are arranged in increasing numerical order, accompanying the alphabetical arrangement of preferred names. Alternative names are also inserted in regular alphabetical order with a blank space in the left hand column and a series of dots leading to the unique number in the right hand column. The preferred name can then be found by referring to that number in the left hand column.

The PESTICIDE REGISTER is a modification of the nomenclature system devised by R. L. Caswell (4), which has been adapted to computerized use. The obvious advantage of the computer for cataloging chemical compounds and for information retrieval has been widely recognized (1, 2). Many manufacturers now have integrated information retrieval systems in their research and development programs (3).

Whereas the present numbering and listing sys-

tem follows Caswell rather closely, very different criteria were involved in selection of preferred names. Caswell's primary concern was official labeling requirements. Herein, first consideration was rapid and unambiguous identification of pesticide chemicals. Trademarked names have been greatly expanded to form a fairly complete cross reference list tied to the chemical names (5, 6). Such listing is for information only; the presence or absence of any trade name does not imply endorsement by Cornell University or by the State of New York.

The already existing Chemical Abstracts Registry numbers comprising 8 to 10 alphanumeric symbols were judged to be too complex for efficient handling of pesticide chemicals alone. Neither the International Union of Pure and Applied Chemistry nor the Chemical Abstracts nomenclature is unambiguous, so that a numerical system is required for computer use to ensure that one and only one number identifies a pesticide chemical having multiple names.

Common names were used whenever they were really well known, but a conservative policy was adopted whenever the use of recently coined names would tend to confuse rather than help. The use of letter abbreviations and serial numbers is convenient inside the product development laboratory, but continued use outside clutters chemical literature. Abbreviations have been limited to a few instances where they are universally understood; i.e., 2,4-D and DDT.

| 8840            | 4-(2,4,5-TRICHLOROPHENOXY)BUTYRIC ACID  |                                 |
|                 | 2-(2,4,5-TRICHLOROPHENOXY)ETHYL 2,2-DICHLOROPROPIONATE (ERBON). . . . .           | 4170                            |
|                 | 2-(2,4,5-TRICHLOROPHENOXY)PROPIONIC ACID (SILVEX) . . . . .                       | 7400                            |

In indexing, minimal use of such abbreviations allows listing first under each letter without confusion. The usual indexing conventions have been followed: ignoring for purposes of alphabetical arrangement those portions of names containing numerals; positional isomers, such as *o*, *m*, *p*, *cis*, *trans*; elemental points of attachment, etc. Forty 2,4-D compounds of widely different physical and phytotoxic properties have been separately listed. By making 2,4-D begin with 2700, dicamba with 2900, silvex with 7400, and 2,4,5-T with 8200, the last two digits of each number coincide with the same acid, salt, or ester of the parent compound. Organic mercury and tin compounds were grouped together after the respective metals: 5200 to 5440 for mercury; and 8590 to 8660 for tin. Inverted nomenclature has been used for salts of organic acids, but the uninverted verbal forms have been retained for inorganic compounds and organic esters, except in a few cases, (1295), where the usual ester nomenclature would be awkward.

Every effort has been made to keep this list as simple as possible. To this end, obsolete chemicals have been deleted; foreign names, experimental, or numbered compounds have been avoided; and, in general, only compounds presently or recently registered for pesticide use by the Federal Government and by the State of New York have been included. Thus, several promising and popular non-chemical means of insect control comprising sex pheromones, juvenile hormones, and chemo-sterilants were omitted until their use by the general public is approved. However, a number of the most common metabolites and decomposition products of pesticide chemicals have been cross-indexed under the parent compound name to facilitate reporting of pesticide residues in the environment.
