\textbf{Abstract.} A theory satisfies the \textit{k-variable property} if every first-order formula is equivalent to a formula with at most \textit{k} bound variables (possibly reused). Gabbay has shown that a fixed time structure satisfies the \textit{k-variable property} for some \textit{k} if and only if there exists a finite basis for the temporal connectives over that structure. We give a model-theoretic method for establishing the \textit{k-variable property}, involving a restricted Ehrenfeucht-Fraisse game in which each player has only \textit{k} pebbles. We use the method to unify and simplify results in the literature for linear orders. We also establish new \textit{k-variable properties} for various theories of bounded-degree trees, and in each case obtain tight upper and lower bounds on \textit{k}. This gives the first finite basis theorems for branching-time models.

1. Introduction

A first-order theory $\Sigma$ satisfies the $k$-variable property if every first-order formula is equivalent under $\Sigma$ to a formula with at most $k$ bound variables (possibly reused). For example, in an arbitrary partial order, five bound variables are needed to express the statement "there are at least five elements below $x,"$ but in a linear order, two variables suffice:

\[(1.1) \exists y \ y < x \land (\exists x \ x < y \land (\exists y \ y < x \land (\exists x \ x < y \land (\exists y \ y < x))))\].

The $k$-variable property is important in temporal logic: Gabbay [G] has shown that a fixed time structure satisfies the $k$-variable property for some $k$ if and only if there exists a finite basis for the temporal connectives over that structure, in the same sense that $\lor$ and $\neg$ form a basis for the propositional connectives.

Kamp [K] showed that any Dedekind-complete linear order with arbitrary monadic predicates admits a finite basis for the temporal connectives. This result was extended to other linear time structures by Stavi [S]. Amir and Gabbay [AG] showed that any definable lexicographic product of time structures admitting a finite basis also admits a finite basis. This result gave the first infinite non-linear structures admitting a finite basis, although up to now no results have been established for trees.

The methods used by these researchers were largely syntactic. In this paper we give a model-theoretic method for establishing the $k$-variable property uniformly for all models of certain first-order theories. The method uses a variant of the Ehrenfeucht-Fraisse game [E,F] which allows each player only $k$ pebbles [I]. Applying this method to the theory of linear order, we are able to unify the results of [K,S]. We also establish new $k$-variable expressiveness results for various theories of bounded-degree trees, and in each case obtain tight upper and lower bounds on $k$. We thus have, by Gabbay’s result [G], the existence of a finite basis for the first-order-expressible branching-time temporal connectives over tree models of bounded degree.

2. A model-theoretic lemma

Let $L$ be a first-order language with individual variables $\{x_1, x_2, \ldots \}$. A partial valuation over a structure $A$ for $L$ is a partial function $u : \{x_1, \ldots \} \to A$. The domain of $u$ is denoted $\partial u$. The cardinality of $\partial u$ is denoted $|u|$. A $(k)$-configuration over $A, B$ is a pair $(u, v)$, where $u$ is a partial valuation over $A$ and $v$ is a partial valuation over $B$ such that
\[ \partial u = \partial v \subseteq \{x_1, \ldots, x_k\} \]. If \((u, v)\) is a \(k\)-configuration and if \(L' \subseteq L\), then \(u\) and \(v\) are said to be \(L'\)-equivalent if they have the same \(L'\)-type; i.e., if for all formulas \(\varphi \in L'\) with free variables in \(\partial u\),

\[ A, u \models \varphi \iff B, v \models \varphi. \]

**Lemma 2.1.** Let \(\Sigma\) be a set of sentences in \(L\). Let \(L', L'' \subseteq L\) such that \(L'\) is closed under the propositional operators. The following two conditions are equivalent:

(i) For all \(A, B\) models of \(\Sigma\) and \(k\)-configurations \((u, v)\) over \(A, B\), if \(u\) and \(v\) are \(L'\)-equivalent, then they are \(L''\)-equivalent.

(ii) For all \(\varphi \in L''\) with free variables among \(\{x_1, \ldots, x_k\}\), there exists a \(\psi \in L'\) such that \(\Sigma \models \varphi \iff \psi\).

**Proof.** (ii) \(\rightarrow\) (i) is immediate. (i) \(\rightarrow\) (ii): If \(\Sigma \cup \{\varphi\}\) is inconsistent, take \(\psi = false\) and we are done. Otherwise, let \(\Gamma\) be an arbitrary complete \(L'\)-type in the variables \(\{x_1, \ldots, x_k\}\) extending \(\Sigma \cup \{\varphi\}\). Then \(\Sigma \cup \Gamma \cup \{\neg \varphi\}\) is inconsistent, otherwise models \(A, u\) and \(B, v\) of \(\Sigma \cup \Gamma\) could be constructed with \(\partial u = \partial v = \{x_1, \ldots, x_k\}\) such that \(A, u \models \varphi\) and \(B, v \models \neg \varphi\), violating (i). Therefore \(\Sigma \cup \Gamma \models \varphi\). By compactness, there exists a \(\psi_\Gamma \in \Gamma\) such that \(\Sigma \models \psi_\Gamma \rightarrow \varphi\). Now \(\varphi\) is covered by all such \(\psi_\Gamma\), in the sense that

\[ \Sigma \models (\bigvee_{\Gamma} \psi_\Gamma) \iff \varphi \]

where the infinitary join is taken over all \(L'\)-types \(\Gamma\) consistent with \(\Sigma\). Again by compactness, there is a finite set \(F\) of such \(\Gamma\) such that

\[ \Sigma \models (\bigvee_{\Gamma \in F} \psi_\Gamma) \iff \varphi \]

so we may take \(\psi = \bigvee_{\Gamma \in F} \psi_\Gamma\). \(\Box\)

We are interested in a special case of the above lemma which applies to the \(k\)-variable property.

Define the quantifier depth of a formula \(\varphi\) to be the depth of the deepest nesting of quantifiers in \(\varphi\). For example, a formula has quantifier depth 0 if it is quantifier-free, and the quantifier depth of the formula (1.1) is 5.

Let \(n, k \geq 0\). Define \(L_{k,n}\) to be the sublanguage of \(L\) consisting of all formulas \(\varphi\) of quantifier depth at most \(n\) containing only variables \(\{x_1, \ldots, x_k\}\). For
example, the formula (1.1) is in $L_{2,5}$. Define

$$L_k = \bigcup_n L_{k,n}.$$ 

Thus $L = \bigcup_k L_k$.

**Definition 2.2.** A first-order theory $\Sigma$ is said to satisfy the $k$-variable property if for all formulas $\varphi \in L$ with free variables among $\{x_1, \ldots, x_k\}$, there exists a $\psi \in L_k$ such that $\Sigma \models \varphi \leftrightarrow \psi$. □

In this special case, Lemma 2.1 gives

**Corollary 2.3.** The following two conditions are equivalent:

(i) For all $A, B$ models of $\Sigma$ and $k$-configurations $(u, v)$ over $A, B$, if $u$ and $v$ are $L_k$-equivalent, then they are $L$-equivalent.

(ii) $\Sigma$ satisfies the $k$-variable property. □

**3. An Ehrenfeucht-Fraïssé game with bounded number of pebbles**

Let $\Sigma$ be a theory in a first-order language $L$ with equality. Assume further that in every model of $\Sigma$, every finitely generated substructure is finite. We have reduced the problem of establishing the $k$-variable property for $\Sigma$ to checking the condition of Corollary 2.3(i). This will done using a modification of the standard Ehrenfeucht-Fraïssé game [E,F,FR] which uses only a bounded number of pebbles [I].

**Definition 3.1** (the game $G(u, v, k, n)$). Let $A, B$ be structures for $L$, $n$, $k \geq 0$, and $(u, v)$ a $k$-configuration. The game $G(u, v, k, n)$ is played by two players, I and II, who take turns placing pebbles on elements of $A$ and $B$. Player I tries to demonstrate that $A$ and $B$ are nonisomorphic, and player II tries to make $A$ and $B$ appear isomorphic. There are $2k$ pebbles, each colored with one of $k$ distinct colors $x_1, \ldots, x_k$, with exactly two pebbles of each color.

The configuration $(u, v)$ denotes that the two pebbles colored $x_i$ are currently occupying $u(x_i) \in A$ and $v(x_i) \in B$, for $x_i \in \partial u$, and that the pebbles colored $x_i \in \partial u$ are not currently in play. The initial configuration is $(u_0, v_0) = (u, v)$. The players alternate, with player I first. Each round consists of a move of player I followed by a move of player II. Player I can select any pebble and place it on an element of either $A$ or $B$. Player II then has to place the other pebble of the same color on an element of the other structure. Play proceeds for $n$ rounds, generating a sequence of configurations $(u_t, v_t)$, $0 \leq t \leq n$. 

-4-
Let

\[ R(u_t, v_t) = \{ (\tau^A, u_t, \tau^B, v_t) \mid \tau \text{ is a term over } \partial u_t \} \subseteq A \times B. \]

Player II wins the game if all the relations \( R(u_t, v_t) \), \( 0 \leq t \leq n \), are local isomorphisms, i.e., if the map \( u_t(x) \to v_t(x) \), \( x \in \partial u \), is well-defined and extends to an isomorphism of the substructures of \( A \) and \( B \) generated by \( \{ u_t(x) \mid x \in \partial u \} \) and \( \{ v_t(x) \mid x \in \partial v \} \), respectively. Otherwise player I wins. \( \square \)

**Definition 3.2.** A forced win for player II is defined by induction on \( n \). Player II has a forced win in \( G(u, v, k, 0) \) if \( R(u, v) \) is a local isomorphism. Player II has a forced win in \( G(u, v, k, n + 1) \) if \( R(u, v) \) is a local isomorphism, and for all legal moves of player I from configuration \( (u, v) \), there exists a legal move of player II resulting in a configuration \( (u', v') \) such that player II has a forced win in \( G(u', v', k, n) \). Player I has a forced win if player II does not. \( \square \)

Intuitively, a player has a forced win if there is always a choice of moves for that player leading to a win, no matter how well his opponent plays.

**Remark.** It is always to player I's advantage to play a pebble not currently on the board, if possible, and to place a pebble on an element not currently covered by another pebble, if possible; from player I's point of view, the more elements of \( A \) and \( B \) that are covered, the better. Any winning strategy for player I that does not satisfy these conditions can be mapped into a winning strategy that does.

**Lemma 3.3.** If player II has a forced win in the game \( G(u, v, k, n) \), then player II has a forced win in the game \( G(u', v', k', n') \), for any \( n' \leq n \), \( k' \leq k \), and \( u' \) and \( v' \) restrictions of \( u \) and \( v \), respectively, to a smaller domain. \( \square \)

We now establish the relationship between the games \( G(u, v, k, n) \) and the \( k \)-variable property. The following is a generalization of [I], Theorem C.1, to structures allowing function symbols, provided that all finitely generated substructures are finite.

**Lemma 3.4.** Let \( A \) and \( B \) be models of \( \Sigma \). Let \( (u, v) \) be a \( k \)-configuration. Then player II has a forced win in the game \( G(u, v, k, n) \) if and only if \( u \) and \( v \) are \( L_{k, n} \)-equivalent.

**Proof.** We prove the lemma by induction on \( n \). For the basis, player II has a forced win in \( G(u, v, k, 0) \) iff \( R(u, v) \) is a local isomorphism iff \( u \) and \( v \)
agree on all quantifier-free formulas of $L_k$ with variables among $\partial u$, i.e., $u$ and $v$ are $L_{k,0}$-equivalent. Now suppose $n > 0$.

($\rightarrow$) Suppose player II has a forced win in the game $G(u, v, k, n)$. It suffices to show that $u$ and $v$ agree on all formulas of $L_{k,n}$ of the form $\exists x_i \psi$. Suppose $A, u \vDash \exists x_i \psi$. Let $a \in A$ such that $A, u[x_i/a] \vDash \psi$. If player I should move the pebble colored $x_i$ to $a$, then player II has a response $b \in B$ such that player II has a forced win in $G(u[x_i/a], v[x_i/b], k, n - 1)$, by Definition 3.2. Since $\psi \in L_{k,n-1}$, by the induction hypothesis, $B, v[x_i/b] \vDash \psi$, thus $B, v \vDash \exists x_i \psi$. A symmetric argument shows that if $B, v \vDash \exists x_i \psi$ then $A, u \vDash \exists x_i \psi$.

($\leftarrow$) If player II does not have a forced win in $G(u, v, k, n)$, then player I does. Thus there is a move for player I, say the pebble colored $x_i$ to $a \in A$, such that for any move for player II, say to $b \in B$, player I has a forced win in the game $G(u[x_i/a], v[x_i/b], k, n - 1)$. By the induction hypothesis, there is a formula $\psi_b \in L_{k,n-1}$ such that $A, u[x_i/a] \vDash \psi_b$ but $B, v[x_i/b] \vDash \neg \psi_b$.

Using the assumption that all finitely generated substructures are finite, a compactness argument gives a uniform bound on the size of substructures generated by $k$ elements in any model of $\Sigma$. This in turn implies that there are only finitely many inequivalent formulas of $L_{k,n-1}$. Thus the infinitary formula

$$\bigwedge_{b \in B} \psi_b$$

is expressible by a formula of $L_{k,n-1}$, and

$$A, u \vDash \exists x_i \bigwedge_{b \in B} \psi_b, \quad B, v \vDash \neg \exists x_i \bigwedge_{b \in B} \psi_b,$$

and $\exists x_i \bigwedge_{b \in B} \psi_b$ is expressible by a formula of $L_{k,n}$. Therefore $u$ and $v$ are not $L_{k,n}$-equivalent. \(\square\)

The following lemma is an immediate consequence of Lemmas 2.3 and 3.4.

**Lemma 3.5.** $\Sigma$ satisfies the $k$-variable property if and only if for all $A, B$ models of $\Sigma$ and $k$-configurations $(u, v)$ over $A, B$, if player II has a forced win in every game $G(u, v, k, n)$, $n \geq 0$, then player II has a forced win in every game $G(u, v, m, n)$, $m \geq k$, $n \geq 0$. \(\square\)
4. Three variables are necessary and sufficient for linear order

In this section we give a single proof that encompasses the results of [K,S], illustrating the Ehrenfeucht-Fraisse game of §3. We consider games played on linear orders with monadic predicates.

**Theorem 4.1.** Linear order satisfies the 3-variable property and does not satisfy the 2-variable property.

*Proof.* For the upper bound, by Lemma 3.5 it suffices to show that for any 3-configuration \((u, v)\), if player II has a forced win in \(G(u, v, 3, n)\), then player II has a forced win in \(G(u, v, k, n)\), for all \(k\). The result holds for any \(k \leq 3\) by Lemma 3.3, so assume \(k > 3\).

We will describe player II’s best strategy in \(G(u, v, k, n)\) and prove the theorem by simultaneous induction on \(n\). For \(n = 0\), the assertion that player II has a forced win in the game \(G(u, v, k, 0)\) says that \(R(u, v)\) is a local isomorphism, which follows immediately from the assumption that player II has a forced win in the game \(G(u, v, 3, 0)\).

Suppose now that \(n > 0\). If \(|u| = |v| < 3\), then for any move that player I might make, let player II respond according to his best strategy in the game \(G(u, v, 3, n)\). If the resulting configuration is \((u', v')\), then by Definition 3.2, player II has a forced win in the game \(G(u', v', 3, n - 1)\). By the induction hypothesis, player II has a forced win in every game \(G(u', v', k, n - 1), k > 0\). Again by Definition 3.2, since the move of player I was arbitrary, player II has a forced win in \(G(u, v, k, n), k > 0\).

If \(|u| = |v| = 3\), renumber the variables if necessary so that \(v(x_1) < v(x_2) < v(x_3)\) and \(u(x_1) < u(x_2) < u(x_3)\). (Note \(R(u, v)\) is a local isomorphism, since player II has a forced win in \(G(u, v, 3, 0)\). If some \(u(x_i) = u(x_j), i \neq j\), then a pair of pebbles can be removed, and we revert to the previous case.) Consider the pair of corresponding regions

\[
\{a \in A \mid a < u(x_2)\}, \{b \in B \mid b < v(x_2)\}.
\]

Associate with this pair of regions the game

\[
G(u_<, v_<, 3, n),
\]

where \(u_<\) and \(v_<\) are \(u\) and \(v\), respectively, restricted to domain \(\{x_1, x_2\}\). Similarly, associate with the pair of corresponding regions

-7-
\{a \in A \mid a \geq u(x_2)\}, \ \{b \in B \mid b \geq v(x_2)\}

the game

\[G(u_\geq, v_\geq, 3, n),\]

where \(u_\geq\) and \(v_\geq\) are \(u\) and \(v\), respectively, restricted to domain \(\{x_2, x_3\}\). By Lemma 3.3, player II has forced wins in both of these games. But \(|u_\leq| = |u_\geq| < 3\), so by a case previously considered, player II has a forced win in the games \(G(u_\leq, v_\leq, k, n)\) and \(G(u_\geq, v_\geq, k, n), k > 0\).

We now describe a strategy for player II in the game \(G(u, v, k, n)\). Assume \(k > n\), so that player I never needs to remove a pebble from the board. The result follows for smaller \(k\) by Lemma 3.3. Whenever player I moves in one of the designated regions of either \(A\) or \(B\), player II responds with his best strategy in the game associated with that region. Player II will then move in the corresponding region in the other structure, since there is always a pebble on \(u(x_2)\). If \((u', v')\) is any subsequent (global) configuration, the restriction of \((u', v')\) to either of the two pairs of regions is a local isomorphism, since player II has a forced win in the game associated with that region. Moreover, all points of the region \(\{a \in A \mid a < u(x_2)\}\) are less than all points of the region \(\{a \in A \mid a \geq u(x_2)\}\), and similarly for \(\{b \in B \mid b < v(x_2)\}\) and \(\{b \in B \mid b \geq v(x_2)\}\). Therefore \((u', v')\) is a local isomorphism. This establishes the upper bound.

To show that two variables do not suffice, we observe that \(Z\) and \(Q\), without monadic predicates, are \(L_2\)-equivalent but not \(L_3\)-equivalent. Player II's winning strategy in \(G(\emptyset, \emptyset, 2, n)\) is as follows: in the first round, player II plays anywhere in response to player I's move. Subsequently, if player I plays a pebble to the left (right) of the pebble on the board, then player II does the same. The structures are not \(L_3\)-equivalent, because \(Q\) is dense and \(Z\) is not, and density is expressible with three variables:

\[\forall x \forall z (x < z \rightarrow \exists y \ y < x < z). \qed\]

5. Theories of bounded-degree trees

In this section we define various theories of bounded-degree trees and establish tight upper and lower bounds on the number of bound variables needed to define any first-order definable formula.

**Definition 5.1.** Consider a language \(L\) with a binary relation symbol \(\leq\) and
equality =, possibly with extra monadic predicates. Let $L^+$ be $L$ augmented with a binary function symbol +. The atomic formula $x \leq y$ is read, "x is a descendant of y" or "y is an ancestor of x". The function + is intended to give the least common ancestor (LCA), or least upper bound with respect to $\leq$.

Consider the following axioms of $L$ and $L^+$. The axioms (i)-(ivd) are expressed in the language $L$, and (vi) is expressed in the language $L^+$.

(i) "$\leq$ is a partial order."
(ii) "$\leq$ is a linear order above any x."
(iii) "Every pair $x, y$ has an LCA."
(ivd) "There is no set of $d+1$ proper descendants of $x$ whose pairwise LCA is $x$.”
(vd) "Every non-leaf $x$ has a set of $d$ proper descendants whose pairwise LCA is $x$.”
(vi) "$x+y$ is the LCA of $x$ and $y$."

The theories $S_d \subseteq L$ and $S_d^+ \subseteq L^+$ describe trees of degree $d$. $S_d^+$ consists of axioms (i)-(vi), and $S_d$ is obtained from $S_d^+$ by omitting (vi). The theories $T_d \subseteq L$ and $T_d^+ \subseteq L^+$ describe trees of degree at most $d$. These theories are obtained from $S_d$ and $S_d^+$, respectively, by omitting axiom (vd).

Note that models of these theories need not be discrete; there is no notion of "child" or "parent".

For $A$ a model of $T_d$, $a, a_1, a_2 \in A$, $a_1, a_2 < a$, define $a_1 \equiv_a a_2$ if $a_1 + a_2 < a$. It follows from the axioms of $T_d$ that $\equiv_a$ is an equivalence relation with at most $d$ equivalence classes, and exactly $d$ if $A$ is a model of $S_d$ and $a$ is not a leaf. These classes are called subtrees of $a$. For $a' < a$, denote the subtree of $a$ containing $a'$ by $T(a, a')$, and the $L_k, n$-type of the pair $(a, a')$ by $\theta_k, n(a, a')$. The latter is a set of formulas of $L_k, n$ with free variables among $x_1, x_2$. For a subtree $T$ of $a$, define

$$\Theta_{k, n}(T) = \{\theta_{k, n}(a, a') \mid a' \in T\}.$$ 

**Lemma 5.2.** Let $\Sigma$ be one of the theories $T_d$, $T_d^+$, $S_d$, $S_d^+$. Let $(u, v)$ be any $k$-configuration, and let $a$ and $b$ be the suprema of \{u(x) \mid x \in \partial u\} and \{v(x) \mid x \in \partial v\}, respectively. Let $f(n)$ be any sufficiently fast-growing function of $n$, and let

$$k = \max(4, d) \text{ if } \Sigma = T_d \text{ or } T_d^+, \max(4, \lfloor d/2 \rfloor) \text{ if } \Sigma = S_d \text{ or } S_d^+.$$
If player II has a forced win in $G(u,v,k,f(n))$, then there is a one-one correspondence between subtrees $A_1, \ldots, A_l$ of $a$ and subtrees $B_1, \ldots, B_l$ of $b$ such that

(i) $\Theta_{k,n}(A_i) = \Theta_{k,n}(B_i)$, $1 \leq i \leq l$,

(ii) $u(x) \in A_j$ iff $v(x) \in B_j$.

Proof. For the case of $T_d$ or $T_d^+$, we show first that $a$ and $b$ have the same number of subtrees. If not, suppose $a$ has more than $b$. We will describe a winning strategy for player I, contradicting the assumption that player II has a forced win in $G(u,v,k,f(n))$. Let player I play a pebble on $a$, if $a$ is not already covered. Then player II must play $b$, otherwise player I wins in at most one move. (It follows from $T_d$ that $a = u(x) + u(y)$ for some $x,y \in \partial u$, and $b = v(x) + v(y)$.) Now let player I successively play pebbles in as many distinct subtrees of $a$ as possible, leaving a pebble on $a$. Player II must respond by pebbling in separate subtrees of $b$, otherwise player I wins in at most one move. Thus, if the number of subtrees of $a$ is less than $d$, or if $d < 4$, we are done. Otherwise, since there are $d$ pebbles, there must be $d$ subtrees of $a$, of which $d-1$ have pebbles, and $d-1$ subtrees of $b$, all of which have pebbles. Now player I removes the pebble from $a$ and places it somewhere in the last subtree of $a$. Player II must play the corresponding pebble on a point in one of the subtrees of $b$, otherwise player I wins immediately. Now there exist pebbled points $b_0, b_1, b_2$ such that $b_0 + b_1 < b_1 + b_2$, whereas for the corresponding points $a_0, a_1, a_2$, $a_0 + a_1 = a_1 + a_2$. Thus player I wins in one more move by pebbling $b_0 + b_1$ with the fourth pebble. Note that $k = \max(4,d)$ pebbles are required for this argument.

The remainder of the argument uses only $\max(4,\lfloor d/2 \rfloor)$ pebbles and works for all four theories under consideration. By the preceding paragraph, we may assume that $a$ and $b$ have the same number of subtrees. We show (i) first. Suppose there is a $\Theta$ such that the number of subtrees $T$ of $a$ with $\Theta_{k,n}(T) = \Theta$ is different from the number of subtrees of $b$ satisfying this property. We will again describe a winning strategy for player I. Note that there must be some $r < \lfloor d/2 \rfloor$ and $\Theta$ such that exactly $r$ subtrees $T$ of $b$ have $\Theta_{k,n}(T) = \Theta$ and the number of subtrees of $a$ satisfying this property is strictly greater than $r$, or vice-versa (without loss of generality, assume the former). As above, player I will pebble in $r+1$ subtrees of $a$ of type $\Theta$, and player II will be forced to play in a subtree of $b$ of type different from $\Theta$. Now there are pebbles on $a'$, $b'$ and at least two other points $a''$, $b''$ such that $a' + a'' = a$ and $b' + b'' = b$, and
$$\Theta_{k,n}(T(a,a')) \neq \Theta_{k,n}(T(b,b')).$$

let $a'' \in T(a,a')$ such that for no $b'' \in T(b,b')$ is $\theta_{k,n}(a,a'') = \theta_{k,n}(b,b'')$. Player I plays $a$ if not already played. Player II must respond with $b$, otherwise player I wins in 1 move. Player I now plays $a''$. Player II must respond with some $b'' < b$, but whatever $b''$ is played,

$$\theta_{k,n}(a,a'') = \theta_{k,n}(b,b'').$$

By Lemma 3.4, player I has a forced win in $G((a,a''),(b,b''),k,n)$ and therefore also in $G(u,v,k,f(n))$, by Lemma 3.3. This is a contradiction.

Finally we show that $\Theta_{k,n}(T(a,u(x))) = \Theta_{k,n}(T(b,v(x)))$. If not, let $a' \in T(a,u(x_1))$ such that $\theta_{k,n}(a,a') \notin \Theta_{k,n}(T(b,v(x_1)))$. (The opposite case is symmetric.) Player I pebbles $a'$ with a pebble of color other than $x_i$, and the argument now proceeds as in the preceding paragraph. □

**Definition 5.3.** For a theory $\Sigma$, define $\text{var}(\Sigma)$ to be the minimum $k$ such that $\Sigma$ has the $k$-variable property, if such a $k$ exists, or $\infty$ otherwise. □

The following results determine $\text{var}(\Sigma)$ exactly for $T_d$, $T_d^+$, $S_d$, and $S_d^+$.

**Theorem 5.4.**

$$\text{var}(T_d) = \text{var}(T_d^+) = 3 \text{ if } d = 1,$$

$$\max(4,d) \text{ if } d > 1.$$

$$\text{var}(S_d) = \text{var}(S_d^+) = 3 \text{ if } d = 1,$$

$$\max(4,\lceil d/2 \rceil) \text{ if } d > 1.$$

**Proof.** The bounds for $d = 1$ were proved in Theorem 4.1. For $d > 1$ and for $\Sigma$ any of the four theories we are considering, define

$$k = \max(4,d) \text{ if } \Sigma = T_d \text{ or } T_d^+,$$

$$k = \max(4,\lceil d/2 \rceil) \text{ if } \Sigma = S_d \text{ or } S_d^+.$$

Let $g$ and $h$ be sufficiently fast-growing functions of $n$ such that $g(n) > f(h(n))$ and $h(n) > g(n-1)$, where $f$ is the function of Lemma 5.2.

We must show that for all $A$ and $B$ satisfying $\Sigma$, and for all $k$-configurations $(u,v)$ over $A$ and $B$, if player II has a forced win in the games $G(u,v,k,n)$ for all $n$, then player II has a forced win in the games $G(u,v,m,n)$ for all $m$ and $n$. We actually show by induction on $n$ that if
player II has a forced win in the game $G(u, v, k, g(n))$, then player II has a forced win in the games $G(u, v, m, n)$ for all $m$.

As in Theorem 4.1, the basis $n=0$ is immediate. Suppose now that the theorem holds for $n-1$. Assume $m>n$, so that player I will never have to remove a pebble from the board. The result will follow for smaller values of $m$ by Lemma 3.3. If $|u| = |v| < k$, let player II respond to any move of player I with an optimal move according to player II's winning strategy in $G(u, v, k, g(n))$. By Definition 3.2, if the resulting configuration is $(u', v')$, then player II has a forced win in $G(u', v', k, g(n-1))$, and $g(n)-1 > g(n-1)$. By Lemma 3.3 and the induction hypothesis, player II has a forced win in $G(u', v', m, n-1)$ for all $m$. Since player I's move was arbitrary, this constitutes a forced win for player II in $G(u, v, m, n)$.

Now suppose $|u| = |v| = k$. As in the proof of Theorem 4.1, we will break the game $G(u, v, m, n)$ up into several smaller games on which player II has a forced win, and combine these strategies to produce a winning strategy for player II on $G(u, v, m, n)$.

Let $\langle u \rangle$ be the smallest subset of $A$ containing all the $u(x)$ and closed under the operation $+$. Let $\langle v \rangle$ be the corresponding set in $B$. Let $a \in \langle u \rangle$, and let $b$ be the corresponding element of $\langle v \rangle$. Let $A_1, \ldots, A_l$ be the subtrees of $a$, and let $B_1, \ldots, B_l$ be the subtrees of $b$, such that

\[ \Theta_{k, h(n)}(A_i) = \Theta_{k, h(n)}(B_i), \quad 1 \leq i \leq l, \]

and such that $u(x) \in A_i$ iff $v(x) \in B_i$. Such a correspondence between the subtrees of $a$ and $b$ exists, by Lemma 5.2.

If $\langle u \rangle \cap A_i \neq \emptyset$, let $a_i < a$ be its supremum. Let $b_i < b$ be the corresponding element of $\langle v \rangle \cap B_i$. In this case we associate the game

(5.5) \[ G((a, a_i), (b, b_i), k, h(n)) \]

with the pair of regions

\[ A_i = \{ a' \mid a' < a_i \}, \]
\[ B_i = \{ b' \mid b' < b_i \}. \]

If $\langle u \rangle \cap A_i = \emptyset$, let $a_i \in A_i$ and $b_i \in B_i$ such that

(5.6) \[ \theta_{k, h(n)}(a, a_i) = \theta_{k, h(n)}(b, b_i). \]
In this case we associate the game

\[(5.7) \quad G((a, a_i), (b, b_i), k, h(n))\]

with the pair of corresponding regions \(A_i\) and \(B_i\). Finally, if \(a\) and \(b\) are the suprema of \((u)\) and \((v)\), respectively, then we associate the game

\[(5.8) \quad G((a), (b), k, h(n))\]

with the regions

\[
A - \{a' | a' < a\}, \\
B - \{b' | b' < b\}.
\]

Observe that the designated regions of \(A\) partition \(A\), and those of \(B\) partition \(B\). We claim that player II has a forced win in each of the games

\[G(u', v', k, h(n))\]

associated with these regions. In case (5.7), this is because of the property (5.6) and Lemma 3.4; in cases (5.5) and (5.8), it is because with \(k\) pebbles and at most 2 moves, player I can force the configuration \((u', v')\) from \((u, v)\) as long as player II is playing optimally, thus player II has a forced win in \(G(u', v', k, g(n) - 2)\) and \(g(n) - 2 > h(n)\). (Here we are using the property that any uncovered \(a \in (u)\) is \(u(x) + u(y)\) for some \(x, y \in \partial u\).) Moreover, \(|u'| = |v'| < k\). Therefore, by a previous case, player II has a forced win in the games

\[G(u', v', m, n), \text{ for all } m.\]

We now combine optimal strategies for player II in all these games, as in Theorem 4.1. Whenever player I plays in one of the designated regions, player II responds in the corresponding region of the other structure, according to his best strategy in the game associated with that region. Player II's play will always be in the correct region, since pebbles are never removed. Let \((u_t, v_t)\) be the sequence of configurations. Since player II has a forced win in each of these games, each \((u_t, v_t)\) restricted to each region is a local isomorphism; and by the choice of regions, if \(u_t(x)\) and \(u_t(y)\) are in different regions, then \(u_t(x) \leq u_t(y)\) iff \(v_t(x) \leq v_t(y)\).

The lower bounds follow from the lower bounds for linear order (Theorem 4.1), the lower bounds for finite trees (Theorem 6.1), and the following
argument that all of var($T_d$), var($T_d^+$), var($S_d$), and var($S_d^+$) are at least 4 for $d > 1$.

Let $d > 1$ and let $A$ be a full $d$-ary tree such that each path has order type $Z + Z$. Let $a_3$ and $a_4$ be two vertices in the lower part of $A$ whose LCA is $a_2$ in the upper part of $A$. Thus the order type of the path from $a_2$ to $a_3$ and from $a_2$ to $a_4$ is $\omega + \omega^R$. Let $a_1$ be the parent of $a_2$, and let $a_0$ be the parent of $a_1$.

Let $B = A$ and consider the game

$$G((a_0, a_3, a_4), (a_1, a_3, a_4), 3, n).$$

Player II has a forced win, since the initial configuration $R(u, v)$ is a local isomorphism (even in the presence of $+$), and for subsequent moves, as soon as player I picks up a pebble, there is an automorphism of $A$ sending the remaining two points on the left to the remaining two points on the right. From then on, player II can always play the image under that automorphism or its inverse of the point that player I plays.

However, player I has a forced win in

$$G((a_0, a_3, a_4), (a_1, a_3, a_4), 4, 2).$$

Player I first pebbles $a_2 = a_3 + a_4$ with the spare pebble on the left, to which player II must respond with $a_2$ with the spare pebble on the right; then player I removes the pebble on $a_3$ on the left and pebbles $a_1$, to which player II has no response. □

6. Finite models

It is interesting to note how the situation changes when we restrict our attention to finite models. Not only does var() change, but the models are definable up to isomorphism. In this case we can give direct proofs of the upper bounds without using the Ehrenfeucht-Fraisse games of §3.

Define $Fin(\Sigma)$ to be the set of finite models of the theory $\Sigma$. For a set of structures $S$, define $var(S)$ to be the minimum $k$ such that $S$ satisfies Corollary 2.3(i).

Theorem 6.1.

(i) $var(Fin(T_d)) = 2$ if $d = 1$, 

-14-
max(3, d) if d > 1.

(ii) \( \text{var}(\text{Fin}(S_d)) = 2 \) if \( d = 1 \) or 2,
     \( \max(3,\lceil d/2 \rceil) \) if \( d > 2 \).

Proof: We first establish the upper bounds. Given a finite tree \( A \), we produce a formula \( \varphi_A(x) \) such that whenever \( B \) is a tree and \( b \in B \), then \( \varphi_A(b) \) holds in \( B \) iff the subtree of \( B \) with root \( b \) is isomorphic to \( A \).

If \( A \) consists of a single node \( a \), we assert that \( x \) satisfies the same monadic predicates that \( a \) does, and that \( x \) has no proper descendants. This takes two variables.

If \( A \) contains at least two nodes, let \( a \) be the root of \( A \) and let \( A_1, \ldots, A_m \) be the maximal proper subtrees of \( A \), with roots \( a_1, \ldots, a_m \), respectively. Assume by induction on height that the formulas \( \varphi_{A_1}(x), \ldots, \varphi_{A_m}(x) \) have been constructed. As above, we first assert that \( x \) satisfies the same monadic predicates that \( a \) does. We then assert that there exist proper subtrees satisfying each of the \( \varphi_{A_i}(x) \):

\[
\bigwedge_{i=1}^{m} \exists y < x \varphi_{A_i}(y)
\]

and that every proper subtree has a supertree satisfying one of them:

\[
\forall y < x \exists x \geq y \bigvee_{i=1}^{m} \varphi_{A_i}(x).
\]

Each of these statements takes two variables. Together they establish the isomorphism types of the maximal proper subtrees. For the cases \( T_1 \) and \( S_1 \), we are done; for the other cases, it remains to show how to specify the number of maximal proper subtrees of each isomorphism type.

Consider the case \( T_d \). Observe that the predicate "\( y \) is a child of \( z \)" is expressible with three variables:

\[
y < z \land \forall x \ y < x \rightarrow z \leq x.
\]

So is the predicate "\( y \) and \( z \) are siblings":

\[
\forall x \ y \text{ is a child of } x \leftrightarrow z \text{ is a child of } x.
\]
If there are \( p < d \) children of \( a \) of isomorphism type \( A_i \), we can express this with the formula
\[
\exists y_1 \cdots \exists y_p \text{ the } y_j \text{ are distinct children of } x \\
\land_{j=1}^p \varphi_{A_i}(y_j) \\
\land \forall x \text{ and } y_1 \text{ are siblings} \land \varphi_{A_i}(x) \rightarrow \lor_{j=1}^p y_j = x.
\]

This takes \( \max(3,p+1) \leq d \) variables. The only case of \( T_d \) not yet covered is when \( a \) has \( d \) maximal proper subtrees, all isomorphic to \( A_1 \). In this case we say that all children \( y \) of \( x \) satisfy \( \varphi_{A_i}(y) \), and there is a child of \( x \) with \( d-1 \) distinct siblings. The variable \( x \) can be used to name one of the siblings. This takes \( \max(3,d) \) variables. This completes the argument for \( T_d \).

Now consider the case \( S_d \). Above, we specified all the isomorphism types of the maximal proper subtrees \( A_i \) of \( A \). If all the \( A_i \) are isomorphic, or if all are of distinct isomorphism types, we are done. This exhausts the case \( d = 2 \), so let \( d \geq 3 \). We will show that \( \max(3,\lfloor d/2 \rfloor) \) variables are sufficient. If all isomorphism types are satisfied by at most \( \lfloor d/2 \rfloor \) of the \( A_i \), then as above we can use \( \lfloor d/2 \rfloor \) variables \( y_j \) to name those \( a_i \) and assert \( \varphi_{A_i}(y_j) \). This takes \( \max(3,\lfloor d/2 \rfloor) \) variables. If there are \( m > \lfloor d/2 \rfloor \) \( A_i \) isomorphic to \( A_1 \), then all other isomorphism types are covered by the preceding case; we can then assert that there are \( d - m < \lfloor d/2 \rfloor \) distinct children of \( x \) not satisfying \( \varphi_{A_i} \), and then use one universally quantified variable to assert that all other siblings satisfy \( \varphi_{A_i} \). In either case we have used \( \max(3,\lfloor d/2 \rfloor) \) variables.

We now establish the corresponding lower bounds. In each of the cases below, we produce two finite models \( A \) and \( B \) of one of our theories \( \Sigma \) such that \( A \) and \( B \) are not elementarily equivalent, but \( A \) and \( B \) are \( L_v \) equivalent, where \( v = \text{var}(\text{Fin}(\Sigma)) - 1 \). In each of the cases below, it is fairly straightforward to determine a winning strategy for player II for the game \( G(\emptyset, \emptyset, v, n) \). We leave this to the reader.

(Case \( T_1 \), \( S_1 \), \( S_2 \), \( v = 1 \).) Let \( A \) and \( B \) be arbitrary nonempty nonisomorphic models with no monadic predicates.

(Case \( T_2 \), \( v = 2 \).) Let \( A \) be the complete binary tree of depth 2, and let \( B \) be the binary tree of depth 2 with two nodes of depth 1, three leaves of depth 2, and no monadic predicates.
(Case $T_d, v = d - 1$.) Let $A$ be the complete $d$-ary tree of depth 1, $B$ the complete $(d - 1)$-ary tree of depth 1, and no monadic predicates.

(Case $S_3, S_4, v = 2$.) Let $A$ and $B$ be complete $d$-ary trees of depth 2. Let $M$ be a monadic predicate such that one of each cluster of leaves satisfies $M$ in $A$, and two of each cluster satisfy $M$ in $B$.

(Case $S_{2k}, k > 2, v = k - 1$.) Let $B$ and $C$ be complete $2k$-ary trees of depth 1. Let $M$ be a monadic predicate true of exactly $k - 1$ leaves in $A$ and $k$ leaves in $B$.

(Case $S_{2k + 1}, k > 1, v = k$.) Let $A$ and $B$ be complete $(2k + 1)$-ary trees of depth 1. Let $M$ be a monadic predicate true of exactly $k$ leaves in $A$ and $k + 1$ leaves in $B$. □
