December 12, 1988

Abstract

The category of L-domains was discovered by Achim Jung [5] while solving the problem of finding maximal cartesian closed categories of algebraic CPO's and continuous functions. In this note we analyse the properties of the lossless powerdomain construction, that is closed on the algebraic-L-Domains. The powerdomain is shown to be isomorphic to a collection of subsets of the domain on which the construction was done. The proof motivates a certain finiteness condition on the inconsistency relations of elements. It is shown that all algebraic CPO’s D whose basis B(D) has property M satisfy the condition. In particular, the coherent L- domains [3] satisfy the condition.
1 Introduction

Recent work by A. Jung and C. Gunter shows that the L-domains discovered independently by A. Jung[5] and T. Coquand[1] forms an interesting ccc. P. Buneman proposed the lossless powerdomain construction that is closed on L-domains. Buneman's construction was based on intuitions from databases. We were studying the construction as a possible candidate for modelling oracleisable indeterminacy. The present paper investigates some purely mathematical questions that arose from the study. Another paper, under preparation, will report on the semantic investigations of indeterminacy, using the new powerdomain.

A representation theorem is proved for the lossless powerdomain in Section 3. The proof suggests the imposition of some natural conditions on L-domains. The proof uses the notion of finite separability, i.e. the ability to separate elements of the sets that constitute the powerdomain by disjoint basic Scott open sets. (This is made precise in Section 3). This suggests that a natural condition to consider is that the inconsistency relation have finite witnesses. Section 4 discusses this notion of finite inconsistency. Discussions with C. Gunter and E. Gunter revealed the relationship of this property to the coherent L-domains[3].

2 Preliminaries

This section outlines the basic definitions and facts that are used in the note.

A subset X of a partially ordered set is directed iff it is non-empty and if every pair of elements in X has an upper bound in X. A partial order D is said to be (directed) complete if every directed subset X of D has a least upper bound in D. We shall only consider CPO's with a least element, which will be denoted \( \perp \). An element \( d \) of \( D \) is said to be compact if for every directed set \( D \) such that \( d \sqsubseteq \bigsqcup D \), there is an element \( x \in D \) such that \( d \sqsubseteq x \). The set of all elements of \( D \) greater than a compact element \( d \) is denoted by \( d \uparrow \). The set of all elements of \( D \) less than an element \( x \) is denoted by \( x \downarrow \). A CPO \( D \) is said to be algebraic if every element is the lub of a directed set of compact elements. The set of compact elements of an algebraic CPO \( D \) is denoted by \( B(D) \). Step functions of the form \( d \backslash e \)
where \( d \) and \( e \) are compact elements of \( D \) and \( E \) respectively are compact elements of the function space \( D \to E \). The set of minimal upper bounds of a subset \( A \) of \( D \) below elements of a subset \( B \) of \( D \) is denoted by \( \text{mub}_A(B) \).

An algebraic CPO \( D \) is said to be an algebraic-L-domain when any of the following equivalent conditions hold [5].

1. For each \( x \in D \), the set \( x \downarrow \bigcap B(D) \) is a \( \vee \)-semilattice with smallest element.

2. For each upper bound \( x \) of a finite subset \( A \) of \( B(D) \), there is a unique minimal upper bound of \( A \) below \( x \).

3. For any finite subset \( A \) of \( B(D) \), \( \text{mub}_A(D) = \text{mub}(\text{mub}_A(D)) \) \( (D) \)

3 The Lossless Powerdomain

The usual power-domain constructions are not closed on L-Domains. Peter Buneman discovered the Lossless Powerdomain construction [2] that is closed on L-domains.

**Definition 1** Let \( D \) be an L-domain. Define the preorder \( P_L(D) \) as follows:

\[
|P_L(D)| = \{(e_1 \ldots e_n) \mid (\forall 1 \leq i \leq n) \ [e_i \in B(D)] \ \land \ (\forall 1 \leq i, j \leq n) \ [i \neq j \implies \text{mub}(e_i, e_j)(D) = \phi]\}
\]

and the elements of \( |P_L(D)| \) are ordered by the Egli-Milner ordering, \( \sqsubseteq_{EM} \).

Actually \( P_L(D) \) is a partial order. The Lossless Powerdomain \( \overline{P_L(D)} \) is constructed by ideal-completion of \( P_L(D) \).

**Lemma 1** \( \overline{P_L(D)} \) is an L-domain if \( D \) is.

**Proof:** It suffices to prove that \( P_L(D) \) is an upper semi-lattice under the partial order \( \sqsubseteq_{EM} \). Let

\[ a = (e_1 \ldots e_n), \ b = (d_1 \ldots d_m), \ c = (f_1 \ldots f_p), \ a, b \sqsubseteq_{EM} c \]

Then, \( \bigcup \{a, b\} \) under \( c \) is given by,
\[ \bigcup \{a, b\} = \bigcup \{ m \cup b(e_i, d_j) \mid 1 \leq i \leq n, 1 \leq j \leq m, e_i \uparrow \cap d_j \uparrow \cap c \neq \phi \} \]

The verification that the above definition is correct is quite easy.

It is shown that the ideals in the lossless powerdomain are representatives of their fringe sets. Fringe sets are the sets generated by following the partial order arrows among the elements of the ideal. The following definition captures the idea of "following arrows".

**Definition 2** A GENERATOR \( d \) over an ideal \( I \in \overline{P_L(D)} \) is a function \( d : I \rightarrow D \) such that:

- \( i \in I \implies d(i) \in i \)
- \( (i \in I \land j \in I \land i \subseteq EM j) \implies d(i) \subseteq d(j) \)

The following lemma is an easy consequence of the definition.

**Lemma 2** If \( d \) is a GENERATOR over \( I \), \( d(I) \) is a directed set in \( D \).

**Definition 3** Let \( I \in \overline{P_L(D)} \). The set generated by \( I \) is

\[ S_I = \{ \bigcup d(I) \mid d \text{ is a Generator on } I \} \]

Since the lossless powerdomain embodies finite branching only, one expects the sets generated to be Scott-compact. The proof requires the following lemma, that is proved using the axiom of choice. (Proof given in appendix)

**Lemma 3** Let \( I \in \overline{P_L(D)} \). Let \( \bar{I} \) be cofinal in \( I \). Let \( P \) be a predicate defined on \( D \) such that

1. \( \forall i \in \bar{I} \) \( \exists e \in i \) \([P(e)] \)
2. \( d \in i \in \bar{I} \land e \in j \in \bar{I} \land i \subseteq EM j \land d \subseteq e \land P(e) \implies P(d) \)

Then there is a generator \( d \) over \( I \) such that \( \forall i \in \bar{I} \) \([P(d(i))] \).

**Lemma 4** If \( I \in \overline{P_L(D)} \), \( S_I \) is non-empty and Scott-compact.

**Proof:**

4
1. Define a predicate $P$ on $D$ by

$$P(e) \iff (\exists i \in I) [e \in i]$$

From lemma 3, we get a generator on $D$. Hence $S_I$ is non-empty.

2. Let $\{x_\alpha\}$ be a net in $S_I$. Define a predicate $P$ on $D$ as follows:

$$P(e) \iff (\exists i \in I) [e \in i \land e \uparrow \cap \{x_\alpha\} \text{ is co-final}]$$

From lemma 3, we get a generator $d$. Consider $\bigsqcup d \{I\}$. Any neighbourhood $e \uparrow$ of $\bigsqcup d \{I\}$ has non-empty intersection with $d \{I\}$, and consequently is cofinal in $\{x_\alpha\}$. Hence $\bigsqcup d \{I\}$ is an accumulation point of $\{x_\alpha\}$.

However, not all non-empty Scott-compact sets are generated by some ideal in the lossless powerdomain. Consider the L-domain in Fig 1. The set $\{x, y\}$ cannot be generated by any ideal in $P_L(D)$, even though the set $\{x, y\}$ is finite and hence compact in the Scott Topology. This observation motivates the following definition.

**Definition 4** $S \subseteq D$ is **FINITELY SEPARABLE** if

$$(\forall S_{fin} = \{x_1 \ldots x_n\}, S_{fin} \subseteq S) (\exists (e_1 \ldots e_m) \in P_L(D)) [n \leq m \land (\forall 1 \leq i \leq n)(e_i \subseteq x_i) \land (e_1 \ldots e_m) \subseteq_{EM} S]$$

The following lemma is an easy consequence of the above definition.

**Lemma 5** If $I \in P_L(D)$, $S_I$ is **FINITELY SEPARABLE**.
It turns out that one can generate all \textit{FINITELY SEPARABLE} and Scott-compact sets.

\textbf{Definition 5} \textit{Let} $L$ \textit{be an L-domain. Then} $\Psi_D$ \textit{is the set of all Scott-compact finitely-separable subsets of} $D$ \textit{ordered by} $\subseteq_{EM}$.

Note that $\Psi_D$ is a partial order. Now, we define maps between $\overline{P_L(D)}$ and $\Psi_D$ in a natural manner, and show that the definitions do indeed constitute an order isomorphism between the partial orders, giving us the required representation theorem.

\textbf{Lemma 6} \textit{Define} $\Phi: \overline{P_L(D)} \rightarrow \Psi_D$ \textit{by}

$$\Phi (I) = S_I$$
Then, $\Phi$ is monotone.

**Proof:** Let $I_1 \subseteq \overline{\overline{P_L(D)}}$, $I_2 \subseteq \overline{P_L(D)}$, $I_1 \subseteq I_2$. Let $\Phi(I_1) = S_{I_1}$, $\Phi(I_2) = S_{I_2}$.

- Let $x \in S_{I_1}$
  \[ \Rightarrow (\exists d \ [\bigcup d(I_1) = x]), \text{ where } d \text{ is generator on } I_1. \]
  Define
  \[ \tilde{I}_2 = \{ i | i \in I_2 \land (\exists j \in I_1) [j \subseteq EM] \} \]
  Note that $\tilde{I}_2$ is cofinal in $I_2$. Define predicate $P$ by
  \[ P(e) \iff (\exists i, j) [i \in \tilde{I}_2 \land e \in i \land j \in I_1 \land d(j) \subseteq e \land e \in i \land i \in \tilde{I}_2] \]
  The generator $d$ on $I_2$ given by lemma 4 satisfies $x \subseteq \bigcup \tilde{d}$
  \[ \Rightarrow (\forall x \in S_{I_1}) (\exists y \in S_{\tilde{I}_2}) [x \subseteq y] \]

- Let $x \in S_{I_2}$
  \[ \Rightarrow (\exists \tilde{d} \ [\bigcup \tilde{d}(I_2) = x]), \text{ where } \tilde{d} \text{ is a generator on } I_2. \]
  Restriction of $d$ to $I_1$ gives a generator $d$ on $I_2$ such that $d(I_1) \subseteq \tilde{d}(I_2)$. Hence, we have \[ (\forall y \in S_{\tilde{I}_2}) (\exists x \in S_{I_1}) [x \subseteq y] \]

**Lemma 7** Let $S \in \Psi_D$, $(e_1 \ldots e_n) \subseteq_{EM} S$, $(d_1 \ldots d_m) \subseteq_{EM} S$. Then

\[ (\forall 1 \leq i \leq n, 1 \leq j \leq m) [mub(e_i, d_j)(S) \text{ is finite}] \]

**Proof:** Let $1 \leq i \leq n, 1 \leq j \leq m$. Consider the basic open cover of $S$ consisting of

- $e_i \uparrow, e_i \in mub(e_i, d_j)(S)$
- $d_j \uparrow, j \neq j, 1 \leq j \leq m$
- $e_i \uparrow, i \neq i, 1 \leq i \leq n$

This open cover has finite subcover. Since all members of $(e_1, \ldots e_n)$ and $(d_1, \ldots d_m)$ are pairwise inconsistent, we deduce that $mub(e_i, d_j)(S)$ is finite.
Lemma 8 Define $\tilde{\Phi} : \Psi_D \rightarrow \overline{P_L(D)}$ by

$$\tilde{\Phi}(S) = \{ (e_1 \ldots e_m) | (e_1 \ldots e_m) \subseteq EM S \wedge (e_1 \ldots e_m) \in P_L(D) \}$$

Then, $\tilde{\Phi}$ is monotone.

Proof:

- We have to first show that $\tilde{\Phi}$ is well defined. Let $S \in \Psi_D$. Then we have
  - $\{\perp\} \subseteq \tilde{\Phi}(S)$. So, $\tilde{\Phi}(S)$ is non-empty.
  - $(e_1 \ldots e_n) \subseteq EM S$, $(d_1 \ldots d_m) \subseteq EM S$
    $$\implies \bigcup \{mub(e_i, d_j)(S)\} \big| 1 \leq i \leq n, 1 \leq j \leq m, e_i \uparrow \bigcap d_j \uparrow \bigcap S \neq \phi\} \subseteq EM S$$. Hence, $\tilde{\Phi}(S)$ is directed.
  - $\tilde{\Phi}(S)$ is obviously downward closed.

Hence, $\tilde{\Phi}(S)$ is an element of $\overline{P_L(D)}$.

- $S_1 \subseteq EM S_2 \implies \tilde{\Phi}(S_1) \subseteq \tilde{\Phi}(S_2)$. Hence, $\tilde{\Phi}$ is monotone. □

Lemma 9 $\tilde{\Phi} \circ \Phi = Id$

Proof: Note that it suffices to prove that

$$(\forall i \in P_L(D)) [i \in I \iff i \subseteq EM S_I]$$

The 'if' part is obvious. For the reverse direction, consider

$$(e_1 \ldots e_m) \in P_L(D) \wedge (e_1 \ldots e_m) \subseteq EM S_I$$

$$\implies (\exists x_1 \ldots x_m \in S_I) (\forall 1 \leq k \leq m) [e_k \subseteq x_k]$$

Let $d_1 \ldots d_m$ be the generators on $I$ corresponding to $x_1 \ldots x_m$. Since $d_k(I)$ is a directed set for all $1 \leq k \leq m$, we have

$$(\forall 1 \leq k \leq m) (\exists i_k) [e_k \subseteq i_k \in I \wedge d_k(i_k) = e_k \wedge e_k \subseteq e_k]$$

Since $I$ is directed, $\exists i \in I [i_1 \ldots i_m \subseteq EM i]$. Note that $\forall 1 \leq i \leq m) (\exists i \in i) [e_i \subseteq e_i]$. Define

$$\tilde{I} = \{ j | j \in I \wedge i \subseteq EM j \}$$
Note that $\tilde{I}$ is cofinal in $I$.

- We have

$$(\forall j \in \tilde{I}) (\forall 1 \leq k \leq m) (\exists e_k \in j) [e_k \sqsubseteq e_k]$$

- We need to prove that $(\exists j \in \tilde{I}) (\forall \bar{e} \in j) (\exists 1 \leq k \leq m) [e_k \sqsubseteq \bar{e}]$ Suppose not. Define predicate $P$ by:

$$P(e) \iff (\exists j \in \tilde{I}) [e \in j \land e_1 \sqsubseteq e \ldots e_m \sqsubseteq e]$$

$P$ satisfies the conditions of lemma 3. The generator yielded by lemma 3 gives an element in $S_I$ that is not greater than any of $e_1 \ldots e_m$. This is a contradiction since $(e_1 \ldots e_m) \sqsubseteq_{EM} S_I$

Hence, we have an element of $I$ above $(e_1 \ldots e_m)$. Result follows by downward closure of $I$.

Lemma 10 \(\Phi \circ \tilde{\Phi} = I_d\)

Proof: Let $I = \tilde{\Phi} (S)$, where $S \in \Psi_D$.

1. Let $d$ be a generator over $I$. We shall prove by contradiction that $(\exists x \in S) [\sqcup d (I) \sqsubseteq x]$. Suppose not. We have the cover

$$\{e \uparrow (\exists i \in I) [e \in i \land e \neq d (i)]\}$$

Since $S$ is Scott-compact, there is a finite sub-cover

$$\{e_k \uparrow (\exists i_k \in I) [e_k \in i_k \land e \neq d (i_k) \land 1 \leq k \leq n]\}$$

Since $I$ is directed,

$$(\exists i \in I) [i_1 \ldots i_k \sqsubseteq_{EM} i]$$

$$\Rightarrow \{e \uparrow | e \in (i - \{d (i)\})\}$$

is a cover of $S$

This is a contradiction, since $i \sqsubseteq_{EM} S$ means that there is an element in $S$ greater than $d (i)$
2. Let $x \in S$. From definition of $\tilde{\phi}(S)$,

$$(\forall i \in \tilde{\phi}(S)) (\exists e_i \in i) [e_i \sqsubseteq x]$$

Also, the $e_i$'s are unique and form a directed set. Hence, a generator $d_x$ can be defined in the obvious way such that $\bigsqcup d_x(I) \subseteq x$.

3. Let $x, y \in S \wedge x \neq y$. Then, from finite separability of $S$ $d_x \neq d_y$, where $d_x, d_y$ are the generators on $I$ defined as above.

4. Now, we shall show that $\bigsqcup d_x(I) = x$. Let $e \sqsubseteq x$. Consider the cover

$$\{b \uparrow| b \in i \in I, \ b \neq d_x(i)\} \cup \{e \uparrow\}$$

Note that the above is a cover because of finite separability. Since $S$ is Scott-compact, we have a finite sub-cover

$$\{b_k \uparrow| b_k \in i_k \in I, \ b_k \neq d_x(i_k), \ 1 \leq k \leq n\} \cup \{e \uparrow\}$$

Since $I$ is directed, $(\exists i \in I)[i_1 \ldots i_n \sqsubseteq_{EM} i]$. Hence, we note that

$$\{b \uparrow| b \in i, \ b \neq d_x(i)\} \cup \{e \uparrow\}$$

is a cover. Hence, we have

$$(\forall y \in S) [d(i) \sqsubseteq y \implies e \sqsubseteq y]$$

Hence, we deduce that we have the open cover consisting of

- $\tilde{e}$, where $\tilde{e} \in i - \{d(i)\}$
- $\tilde{m}$, where $\tilde{m} \in mub(d(i), e)(S)$

The above open cover has a finite sub-cover,. Hence we deduce that $mub(d(i), e)(S)$ is finite. Hence $\tilde{i}$ defined as

$$\tilde{i} = mub(d(i), e)(S) \cup (i - \{d(i)\})$$
satisfies $\bar{i} \subseteq_{EM} S \land \bar{i} \in P_L(D)$. Hence, $e \subseteq \top \cup d_x (I)$

The above shows that the generators on $I$ generate precisely the elements of $S$. Hence,

$$\Phi \circ \Phi = Id.$$  

\textbf{Theorem 1} \(P_L(D)\) is isomorphic to \(\Psi_D\)

\section{Finitely Detectable Inconsistency}

Consider the elements $x$, $y$ in Figure 1. Every pair of finite elements $e_x$, $e_y$ below $x$, $y$ respectively have upper-bounds. However $x$, $y$ do not have an upper bound. One might demand that the inconsistency relation have finite witnesses, to make it continuous. The above discussion motivates the following definition.

\textbf{Definition 6} An algebraic CPO $D$ is said to have property $FI$ (for finitely detectable inconsistency) if

$$(\forall x, y \in D) \ [mub(x,y) (D) = \phi \implies (\exists e_x, e_y \text{ compact}) \ [e_x \subseteq x \land e_y \subseteq y \land mub(e_x,e_y) (D) = \phi;)]$$

It is easy to check that all Scott-Domains have the above property. C. Gunter observed that all coherent L-domains [3] have property $FI$. The following lemma due to Achim Jung [4] enables us to prove a stronger result.

\textbf{Lemma 11} An algebraic CPO $D$ is Lawson-compact if and only if $B(D)$ has property $M$.

\textbf{Lemma 12} Let $D$ be an algebraic CPO such that every finite subset of $B(D)$ has a complete finite set of minimal upper bounds. (i.e $B(D)$ has Property $M$). Then, $D$ has property $FI$.

\textbf{Proof:} Let $x, y \in D$. Let \(\{d_j| j \in I_x\}\) and \(\{e_i| i \in I_y\}\) be the compact elements approximating $x, y$ respectively, where $I_x$ and $I_y$ are index sets. Furthermore, let us assume that
\[(\forall d_j, e_i) \ [j \in I_x \land i \in I_y \implies mub(d_j, e_i)(D) \neq \phi]\]

Let \(C = \{\{e; \uparrow\} \mid i \in I_y\} \cup \{\{d_j \uparrow\} \mid j \in I_x\}\). Then \(C\) is a collection of closed sets in the Lawson Topology on \(D\) satisfying the finite intersection condition. Result follows from the compactness of the Lawson Topology on \(D\).

In particular all SFP objects \(D\) have property FI.

**Future Work**

The lossless powerdomain construction promises to provide the mathematical foundations for a fully-abstract semantics for languages with finite nondeterminism in which infinite objects are observable in the operational semantics (e.g.) the language of streams and finite-nondeterminism as in[6]. As part of the mathematical justification, we are working on developing a universal characterisation of the construction. A related question about L-domains that we are examining, is the existence of a first-order, information system like representation for algebraic L-domains.

**Acknowledgements**

I would like to thank Prof. Panangaden for invaluable guidance. Indeed, most of the ideas in the representation theorem arose during discussions with him. The original conjecture that all coherent L-domains satisfy property FI is due to Prof. Gunter. The section on finitely detectable inconsistency is based on discussions with Prof. Gunter and Prof. Elsa Gunter during their visit to Cornell. I would like to thank Prof. A. Jung for pointing out an error in the original version of this note and for motivating the general topological structure of the proof of Lemma 12.

Appendix

Lemma 13 Let $\beta$ be a limit ordinal. Let $S_\alpha$ be a sequence of finite sets over $\alpha \in \beta$, such that $\alpha_1 \leq \alpha_2 \Rightarrow S_{\alpha_1} \subseteq S_{\alpha_2}$. Then

$\bigcap (\forall \alpha \in \beta) S_\alpha \neq \emptyset \Rightarrow \alpha < \beta S_\alpha \neq \emptyset$

Proof: Induction on the size of $S_{\alpha_0}$. □

Lemma 14 Let $I \in \overline{P_l(D)}$. Let $S^\alpha_i$ be a collection of non-empty finite sets indexed by $i \in I$, such that

1. $S^\alpha_i \subseteq i$
2. $e_i \in S^\alpha_i, i \subseteq j \Rightarrow (\exists e_j \in S^\alpha_j)(e_i \subseteq e_j)$
3. $(e_i \in S^\alpha_i, j \subseteq i) \Rightarrow (\exists e_j \in S^\alpha_j)(e_j \subseteq e_i)$

Then, either

- $(\forall i \in I) |S^\alpha_i| \neq 1$, or
- There is a collection of non-empty sets $S^\alpha_i + 1$ such that
  - $(\forall i \in I) [S^\alpha_i + 1 \subseteq S^\alpha_i]$
  - The new collection of sets $S^\alpha_i + 1$ has properties 1...3.
  - $(\exists i \in I) [S^\alpha_i + 1 \neq S^\alpha_i]$

Proof: Choose $i \in I$ such that $|S^\alpha_i| \neq 1$. Let $e \in S^\alpha_i$. Define

- $S^\alpha_i + 1 = S^\alpha_i - \{e\}$
- For $j \in I$ such that $i \subseteq EMj$, $S^\alpha_j + 1 = S^\alpha_j - \{\bar{e} | e \subseteq \bar{e}\}$
- For other $k \in I$,
  
  $S^\alpha_j + 1 = S^\alpha_j - \{\bar{e} | (\forall j)(i \subseteq EMj \Rightarrow S^\alpha_j + 1 \cap \bar{e} \uparrow = \emptyset)}$.
The details that the constructed sets satisfy properties is extensive case analysis and is omitted. ■

Lemma 15 Let $I$ be an ideal in $\overline{P_L(D)}$. Let $\bar{I}$ be cofinal in $I$. Let $P$ be a predicate defined on $D$ such that

1. $(\forall i \in \bar{I}) (\exists e \in i) [P(e)]$

2. $(d \in i i \in \bar{I} \land e \in j \land j \in \bar{I} \land i \sqsubseteq_{EM} j \land d \subseteq e \land P(e)) \implies P(d)$

Then, $(\forall i \in \bar{I}) (\exists e_i \in i) [P(e_i) \land (\forall j \in \bar{I}) (i \sqsubseteq_{EM} j \implies (\exists e_j \in j) (e_i \subseteq e_j \land P(e_j)))]$.

Proof: (By contradiction)
Let $i = (e_1 \ldots e_k, e_{k+1} \ldots e_m) \land i \in I$. Let

- $(\forall s) (1 \leq s \leq k) P(e_s)$
- $(\forall s) ((k + 1) \leq s \leq m) \neg P(e_s)$

From assumption
$(\forall s = 1 \ldots k) (\exists j_s) (i \sqsubseteq_{EM} j_s \land (\forall e \in j_s) [(e_s \subseteq e) \implies \neg P(e)]]$

Since $I$ is directed and $\bar{I}$ is cofinal in $I$, $(\exists j \in \bar{I}) (j_1 \ldots j_k \sqsubseteq_{EM} j)$. From assumption on $P (\exists e \in j) P(e)$.
Let $e_{j_1} \in j_1 \sqsubseteq e, \ldots, e_{j_k} \in j_k \sqsubseteq e$

$\implies e_1 \sqsubseteq e_{j_1}, \ldots, e_k \sqsubseteq e_{j_k}$

$\implies e_1 \ldots e_k \subseteq e$

$\implies (\exists e_s \in i) (s > k \land e_s \subseteq e)$

$\implies P(e_s)$ (Contradiction) ■

Lemma 16 Let $I \in \overline{P_L(D)}$. Let $\bar{I}$ be co-final in $I$. Let $d$ be a function $d: \bar{I} \to D$ such that:

- $i \in \bar{I} \implies d(i) \in i$

- $(i \in \bar{I} \land j \in \bar{I} \land i \sqsubseteq_{EM} j) \implies d(i) \subseteq d(j)$

Then, $d$ can be uniquely extended to a generator on $I$.

Lemma 17 Let $I \in \overline{P_L(D)}$. Let $\bar{I}$ be cofinal in $I$. Let $P$ be a predicate as in lemma 15. Then there is a generator $d$ over $I$ such that $(\forall i \in \bar{I}) [P (d(i))]$.
Proof: Define $S^0_i = \{ e \mid e \in i, \ P(e) \}$, where $i \in \tilde{I}$. Note that the collection $S^0_i$ satisfies the conditions of the lemma 15. Let $\Pi$ be the set of all collections $S^\gamma_i$ such that

- The collection $\{ S^\gamma_i \}$ satisfies the conditions of the lemma 14.
- $S^\gamma_i \subseteq S^0_i$ for all $i \in \tilde{I}$

Let $C_1, C_2 \in \Pi$, where $C_1 = \{ S^\gamma_i \}$ and $C_2 = \{ S^\delta_i \}$.
Define $C_1 \preceq C_2$ if $(\forall i \in I) \ S^\gamma_i \subseteq S^\delta_i$

Note that every chain in $\Pi$ has an upper bound by lemma 13. Using Zorn's lemma, we deduce that $\Pi$ has a maximal element. However, from lemma 14, the maximal element $C = \{ S^\alpha_i \}$ satisfies the condition that $(\forall i \in I) [ | S^\alpha_i | = 1 ]$. From the conditions on the elements of $\Pi$ and from lemma 16, we observe that $d$ defined by

$$d(i) = e, \text{ where } e \text{ is the unique element in } S^\alpha_i$$

can be uniquely extended to a generator on $I$.
