1998 DATA BOOK TABLE LISTING KEY		70

Overview

The Pension Benefit Guaranty Corporation (PBGC) was established by the Employee Retirement Income Security Act of 1974 to ensure that participants in defined benefit plans receive their pensions even if their plans terminate without sufficient assets to pay promised benefits. Separate insurance programs protect participants in single-employer and multiemployer plans.

PBGC has published the *Pension Insurance Data Book* annually since 1996 to present detailed statistics on PBGC operations and benefit protection. For the first time, the *Data Book 1998* includes data on the PBGC multiemployer pension insurance program as well as updates of the single-employer data presented previously.

In addition to tabular presentations of current and historical data, this edition features two articles on critical topics for the future of PBGC. The first article focuses on trends in retirement plan choice in the private sector, particularly the shift away from defined benefit plans, which are insured by PBGC, and the reasons behind this change. The second article describes the Pension Insurance Modeling System (PIMS), an advanced simulation model designed to improve the accuracy of PBGC's estimation of its risk and exposure.

We have included in Appendix S all the tables from last year's edition relating to PBGC's single-employer program, but rearranged them into subject categories to make it easier for the reader. Because this represents a change in the ordering of tables from previous years, we have provided an index relating each table to its respective table number in prior editions at the back of the book. We have also, for the first time, included tables of multiemployer data in Appendix M.

Trends in Defined Benefit Plans

Executive Summary

Since the early 1980s, there has been a gradual shift away from defined benefit plans in the private sector. Unless otherwise indicated, the data discussed in this chapter describes these trends for single-employer pension plans and participants. These trends, which generally are unfavorable to the defined benefit universe, are partly due to shifts in employment patterns, but there has been an equally strong reduction in employer preference for defined benefit plans in all sectors of the economy.

This chapter describes the trend away from defined benefit plans among private single-employer pension plans. The number and size distribution of plans, and the number and composition of participants in these plans, have changed markedly since 1980.

The Trend in Number of Plans

Figure 1 shows the number of plans insured by PBGC from 1980 to 1998. The number peaked in 1985 at about 112,000. Since then there has been a sharp decline to about 42,000 plans in 1998. The reduction has not been proportional across all plan sizes. Plans with fewer than 100 participants have shown the most marked decline, from about 90,000 in 1985 to about 27,000 in 1998. There also has been a sharp decline for plans with between 100 and 999 participants. In 1985, there were more than 18,000 plans in this size range but, by 1998, only about 11,000 were operating, a reduction of about 40 percent. These numbers are shown in panel a of **Figure 2**.

Panel b of the figure shows the number of large plans over time. In marked contrast to the trends for plans with fewer than 1,000 participants, the number of plans with more than 1,000 participants has shown modest growth. Since 1980, the number of plans with between 1,000 and 9,999 participants has grown by about 15 percent, from 3,223 to 3,713 in 1998. The number of plans with at least 10,000 participants has grown from 349 in 1980 to 544 in 1998, an increase of over 50 percent; most of this growth has occurred since 1985.

The growth in the number of large plans is attributable to two factors. First, the rapid increase in inactive participants (retirees and separated vested participants) has pushed some plans into higher size categories (see below). Second, there has been considerable plan merger activity over the period.¹

¹ We selected a random sample of 250 plans with at least 500 participants in 1987 and tracked their disposition through 1995. We confirmed that plan mergers and growth in inactive participants each explained a substantial portion of the increase in the number of large plans.

b

The Trend in Number of Participants

In contrast to the dramatic reduction in the total number of plans, the total number of participants in defined benefit plans has shown modest growth. In 1980, for example, there were 27.6 million participants in defined benefit plans. By 1996, this number had increased to almost 33 million.

These numbers, however, mask the negative trend in the defined benefit system because total participants include not only active workers but also retirees (or their surviving spouses) and separated vested participants. The latter two categories of participants are reflective of past coverage patterns in defined benefit plans. A better forward-looking measure is the trend in the number of active participants: these are workers earning pension accruals currently. Here, the numbers are far less encouraging.

Figure 3 shows the total number of active participants in the four plan-size categories for selected years.² Since PBGC data do not reflect the breakout of participants by type,

² Size categories are measured by the number of active participants.

we rely on form 5500 data, which are available through 1996. In 1980, about 73 percent of all active participants in insured single-employer defined benefit plans were in plans covering at least 1,000 workers; by 1996, this percentage had grown to almost 85 percent. Thus, small- and medium-sized plans are becoming progressively less important in the defined benefit system, in terms of both number of plans and number and percent of all active participants.

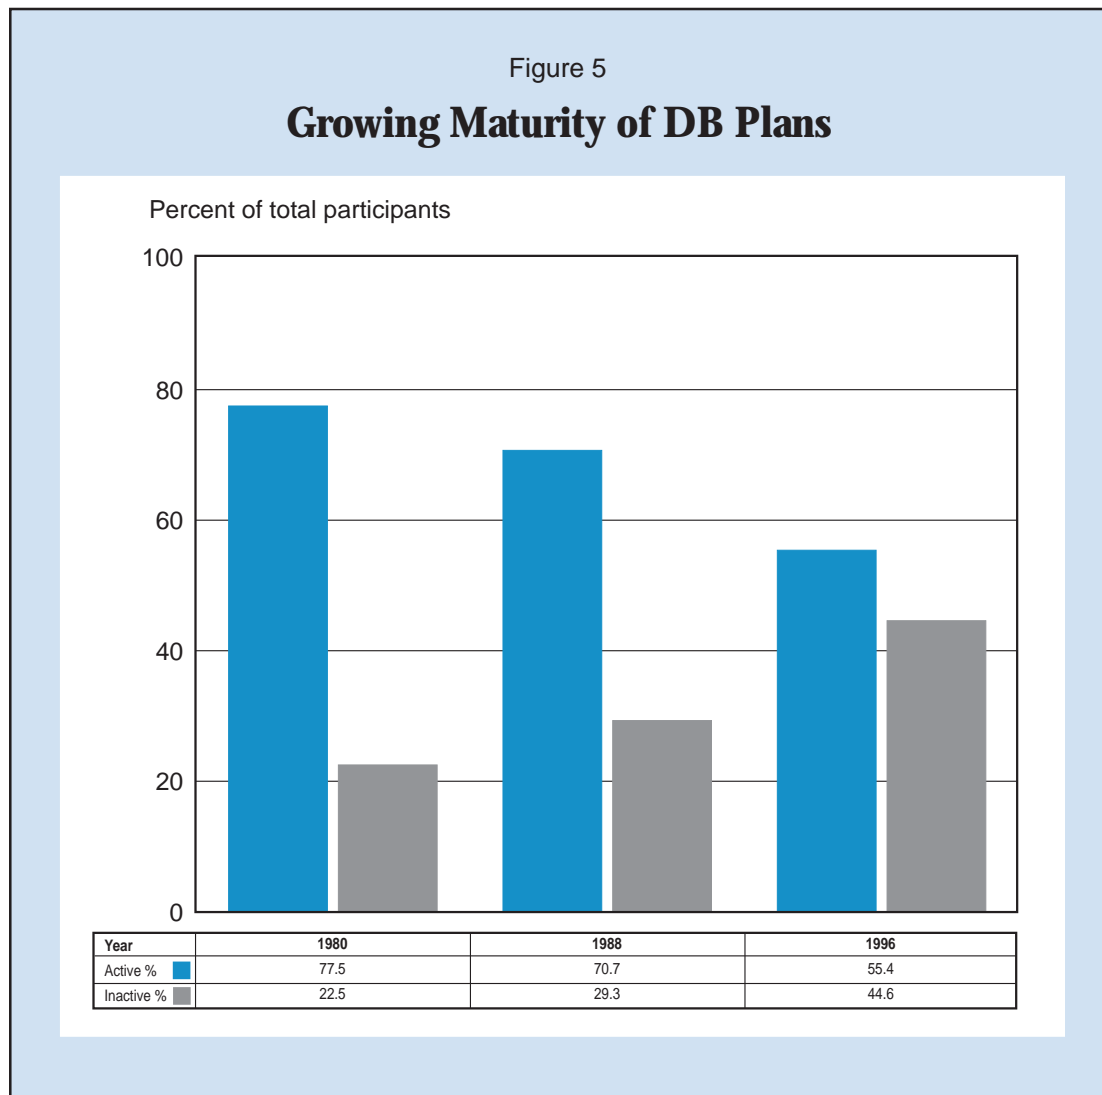

Figure 4 shows the composition of participants by type. The bottom portion of the bar distributions denotes the number of active participants. The middle and top portions denote retirees and separated vested participants, respectively. It is apparent from inspection that the number of active participants has been declining since the late 1980s. In 1988, there were 22.2 million active participants in DB plans; by 1996, this number had fallen to 18.1 million, a decrease of almost 20 percent. At the same time, the number of inactive participants has been growing at a rate sufficient to more than offset the decline in workers in the system. This trend means that the maturity level of the defined benefit system has been rapidly increasing.

For example, in 1980, inactive participants accounted for only 22 percent of total participants in defined benefit plans; by 1988 this number had increased to 29 percent. By 1996, almost 45 percent of the participants in defined benefit plans were inactive participants (see **Figure 5**). If this trend continues, active workers in these plans soon will be a minority of participants.

Percent of Covered Workers

The reduction in absolute numbers of active workers covered by defined benefit plans takes on even more significance when consideration is given to the overall growth in the labor market. Since 1980, the private labor force has grown at the rate of about 1.8 percent per year. The pension-covered private work force grew at about the same rate.

Hence, the overall pension coverage rate remained at approximately 45 percent.³ In this context, the absolute reduction in defined benefit coverage of workers implies a dramatic reduction in the share of workers covered by these plans. In 1980, for example, including workers covered by multiemployer plans, 38 percent of private-sector workers were covered by a DB plan. By 1995, this number had fallen to only 23 percent (see **Figure 6**).

³ See U. S. Department of Labor, Pension Plan Bulletin, No. 7, Spring 1998, table E4. These data include part- and full-time workers. If only full-time workers are counted, the coverage rate is approximately 50 percent.

Figure 7 shows primary coverage rates for single-employer pensions by plan type over the period 1979 to 1998. At the beginning of this period, defined benefit plans were the primary pensions for over 80 percent of pension-covered private sector workers. By 1998, this share had fallen to less than 50 percent. Much of the growth in defined contribution coverage comes from a special kind of defined contribution plan, the 401(k) plan, introduced in the early 1980s.

In particular, over this period, traditional defined contribution plans (that is, those without a 401(k) component) increased their share of covered workers in the primary pension market from 17 to 25 percent. More dramatically, 401(k) plans, which were nonexistent in 1979, had captured 25 percent of the primary pension market by 1996. That is, in 1996, one in every four covered workers in the single-employer universe was covered primarily by a 401(k) plan (see **Figure 8**).⁴

⁴ This number excludes workers who had a 401(k) plan but chose not to contribute. The U. S. Department of Labor does not include non-contributors in their pension-covered counts.

Employment Shifts and Preference Changes

Part of the shift away from defined benefit plans reflects employment shifts from traditional defined benefit firms and industries (for example, large, unionized firms in the manufacturing sector) to firms and industries that traditionally favored defined contribution plans (for example, smaller, nonunion firms in the service sector). Several studies have estimated that upwards of 50 percent of the lost defined benefit share may be attributable to these shifts. The remainder of the shift is attributable to changes in employer preferences away from defined benefit plans in all sectors of the economy. While these preference shifts are somewhat different across sectors, the overall direction is the same in virtually every category of plan coverage.

Pension Insurance Modeling System: An Introduction

Executive Summary

The Pension Insurance Modeling System (PIMS) is a stochastic simulation model developed by PBGC to quantify its risk and exposure over the long run. Like other insurers of catastrophic risk (such as those that cover hurricanes and earthquakes), PBGC is vulnerable to large losses that occur with relatively low probabilities. In these kinds of insurance, past claims are not necessarily a good guide to possible future experience. It is more informative to model the underlying processes that give rise to claims and to take advantage of state-of-the-art computer technology to assess future potential problems. PIMS cannot predict future experience but it can assign probabilities to various potential future loss levels and assist the agency in making assessments about policy alternatives.

Historically, PBGC has forecast its future financial position by assuming that past experience captures the full risk facing the program. Two forecasts (which have been published in the agency's annual report) have reflected the average of past claims. One reflected claims over PBGC's entire history (forecast 'A'); the other reflected PBGC's more recent history (forecast 'B'). Forecast 'C' took a different approach. It assumed that all pensions sponsored by companies with below-investment-grade bond ratings would present claims to PBGC over the ensuing ten years. None of the forecasts assigned probabilities to the results.

In its 1998 Annual Report, PBGC moved to a new and analytically more powerful tool to assess risk. The Pension Insurance Modeling System — PIMS — is a stochastic (randomly determined) simulation model designed to quantify the amount of risk facing the program. The model does not predict future claims. Rather, by fully exploiting the historic relationships of key economic variables, the model assigns probabilities to various levels of potential claims.

The Essence of the Problem

The dominant problem in assessing PBGC's risk is the large variance in potential claims. In many lines of insurance, claims per annum are predictable within a small range. Fire insurance is a good example. Each insured house has a relatively small value and most fires are random events that affect only one house or a handful of insured houses. In most years, x percent of insured houses will suffer serious fire damage per period, with very little variance.

At the other extreme, catastrophic insurance tends to experience wide fluctuations in claims. Hurricane and earthquake insurance are good examples. In most years, damages are quite low. Occasionally a big event occurs, like Hurricane Andrew or the San Francisco earthquake. These are low probability events but, when they occur, they have catastrophic consequences. In these kinds of insurance, losses over past periods may not provide much information about future potential loss levels.

The events that PBGC insures against also have the possibility of catastrophic outcomes. There are two ways in which catastrophic loss levels can occur. First, in periods of poor equity returns, exposure and bankruptcies tend to increase, creating the potential for substantial claims. We call this systematic, or market, risk. Second, some companies can incur adverse financial conditions independent of market returns. Since many insured plans are very large, a small number of bankrupt plan sponsors can generate large claims. We call this idiosyncratic, or random, risk.

Presumably, the probability of a catastrophic event is low, but the losses that could occur in these events arguably dominate PBGC's potential future costs. The rarity of catastrophes means that historical loss events are of limited use in gauging the probabilities of claims levels that might arise in future periods.

The General Approach

When historical data do not adequately describe the insurance risk, a commonly accepted alternative is to model the process that generates uncertainty in the insurance. For example, in the case of hurricane insurance, weather models can be used to simulate thousands of possible hurricane 'seasons.' While these simulations cannot predict when and where hurricanes will develop, they can assess the probabilities that hurricane damage can approach particular levels.

PIMS does for pension insurance what weather models do for hurricane insurance. Given the low probability of bankruptcy and the large number of underfunding paths that could be observed over some time period, we can learn very little by simply observing our history. PBGC's experience is the result of one particular historical path of stock

returns and interest rates, and a few large firms that entered bankruptcy. But other information is available to help us quantify the amount of risk facing the program.

Looking forward, many paths of underfunding are possible, and many combinations of bankruptcies are possible within any path of underfunding. We do not know which particular underfunding path will develop, nor do we know which particular firms might enter bankruptcy. If we are willing to assume, however, that the process that generates historical volatility in key variables is reasonably representative of the process that governs future volatility, we can evaluate the likelihood that various economic scenarios can develop. By modeling real pension plans and incorporating minimum funding rules, we can quantify the likelihood that various levels of exposure can develop under these conditions.

In short, while historical data do not predict future losses, they reveal information that can be used to establish probabilities that certain exposure levels can develop. By evaluating historical bankruptcy data in the same way, we can quantify the potential loss distribution that characterizes insurance coverage.

Stock Returns and Interest Rates

The most important variables in the model are stock returns and interest rates. Historically, the mean real stock return is about 9 percent per year with a standard deviation of 21 percent.¹ Stock returns are independent from one period to the next. This means that we can think of the process as loading an urn with lots of balls, each assigned a return that comes from a distribution that reflects past experience. To determine a simulated sequence of stock returns, PIMS does the equivalent of selecting balls at random from this urn.²

Unlike stock returns, interest rates are correlated over time. We do not observe interest rates of 6 percent one year followed by a 20 percent interest rate the next year and then 2 percent the year after, and so on. But interest rates can gradually move from 6 percent to either 20 percent or 2 percent over several years.

While there are many ways to model interest rates, one easy way that preserves the general character of movements of these rates over time is a simple ‘random walk’ model. This model says that the interest rate next year is expected to be equal to the interest rate this period, plus or minus some random amount. To obtain a distribution of these

¹ The real stock return equals the nominal return, minus the inflation rate. The average return is measured over the period 1926-1997. The mean real return is the simple average of all returns observed over the period. About 95 percent of the returns are within two standard deviations of the mean.

² In this analogy, the balls would be replaced after each draw.

random amounts, we calculate the observed changes in interest rates between years over a long period of history and load this information in the data base. Each year of a simulation, PIMS makes a random draw of these “noise” terms to generate some change in interest rates each year.³

Bankruptcy Rates

The second component of claims events is bankruptcy. When a firm with an underfunded pension plan enters bankruptcy and is in sufficiently poor financial health, underfunding can become a claim against PBGC.

We can observe historical bankruptcy rates among firms that sponsored defined benefit plans over the period 1980-1997. Typical bankruptcy rates for sponsors of defined benefit plans were around one percent per year, less for very large firms, more for smaller firms. The probability also varied as a function of the sponsor’s key financial ratios. In particular, the firm’s likelihood of bankruptcy was lower the higher its equity-to-debt ratio and the higher its cash flow as a percent of company assets. Bankruptcy probabilities also varied significantly over time as a function of overall economic conditions.

PIMS models bankruptcies in the following way. We measure the historical relationship between the probability of bankruptcy and firms’ financial ratios and levels of employment. We also calculate the amounts by which firms’ employment levels and financial ratios can change from period to period, and load this information into the data base. When each firm is simulated each period, its employment level can either increase or decrease and its financial ratios can either improve or deteriorate. The sponsor’s simulated employment level and its simulated financial ratios determine its probability of bankruptcy in any given period.

In this way, we calculate each firm’s chances of going bankrupt each period in the simulation. Each firm has a varying probability of bankruptcy during each year of every scenario; in some scenarios, a firm might develop serious financial difficulty, increasing its odds of going bankrupt, or it might experience a financial turnaround and become a very low risk to the pension insurer.

The model determines which firms enter bankruptcy by using a stochastic process. That is, if a firm has a one percent chance of bankruptcy then it draws a ball from an urn

³ This specification of interest rates has three attractive properties: (1) the expected future interest rate is equal to the (observed) interest rate at the start of the simulation, (2) the simulated rate can follow an infinite number of orderly paths over time, and (3) the variance of the simulated interest rate increases with time so that interest rates in period ten of the simulation can drift quite far from the starting point (in either direction), reflecting growing uncertainty of interest rates far in the future.

filled with 100 balls numbered 1 to 100. If it draws the ball marked '1' then it enters bankruptcy. If it draws a ball numbered 2 or higher, it survives to experience the next period, at which point it is reevaluated, and so on. We assume that, in a bankruptcy in the simulation, any pension plan that has a funding ratio less than 80 percent (on a termination basis) becomes a claim to PBGC.⁴

Pension Data

The PIMS data base has approximately 400 pension plans, sponsored by about 250 firms, which represent about 50 percent of liabilities and underfunding in the defined benefit plan system. Each plan is loaded in the data base in great detail, so that we can realistically model plan liabilities. Each plan is assigned an asset allocation so that pension asset returns can be modeled given any combination of simulated interest rates and stock returns.⁵ The key financial ratios of the plan sponsors also are recorded in the data base.

The plans in the data base represent about half of the liabilities and underfunding among the insured universe. To achieve a universe estimate, we assign one 'partner' plan to each PIMS plan. This mirror plan is identical to its partner plan in the PIMS data, but its sponsor's financial condition changes independently over time. In this way, the model delivers results that are representative of the universe.⁶

The Simulation

We draw a series of stock returns and interest rates for 10 simulated years. We call this an economic scenario. Each plan sponsor is simulated in the scenario; each draws new financial ratios and employment levels every year and has some assigned bankruptcy probability based on these values. The model determines stochastically if the firm enters bankruptcy during the scenario.

We also model each sponsor's pension plan during the scenario. The equity return

⁴ Pension plans with funding ratios in excess of 80 percent are assumed to become sufficient terminations.

⁵ Briefly, we exploit information from the historic form 5500 pension plan annual reports (over the period 1980-1995) to infer investment returns for a sample of pension plans compared to market returns. This exercise yields estimates of asset allocations across pension plans. Using this information, we assign each firm a different asset allocation at the start of every scenario.

⁶ We check various key variables to make sure the sample is correctly calibrated. For example, the overall predicted probability is calibrated, if necessary, to properly reflect bankruptcy probabilities of all DB plan sponsors in the Compustat data. In addition, we check the flat and variable rate premium (VRP) revenues against PBGC collections to ensure that starting values correctly reflect overall premium revenues.

and interest rate draws affect pension assets and liabilities; so do movements in the firm's simulated employment level. By also including the minimum funding rules, we can calculate paths in underfunding that could occur within the constraints of the existing funding rules. If a plan sponsor enters bankruptcy in the model, then we calculate underfunding for guaranteed benefits in its pension plan(s). If any plan meets the 80 percent (or less) funding criterion, it becomes a claim on PBGC.

To increase the amount of information gained from each economic scenario, each plan sponsor is 'cycled' several times through the scenario with different draws on its financial ratios. In this way, many different firms have a chance to enter bankruptcy given a particular sequence of equity returns and interest rates. Experiments show that the model requires 3,000 simulations (300 scenarios, 10 cycles each) to generate stable results.

Claims Potential

The results are characterized by a wide variance. Median claims are about \$600 million per annum (expressed in today's dollars), meaning that half of the simulations produce results higher than this, and half below. The mean level of claims (that is, the average claim) is much higher, more than \$900 million per year. The mean is higher because there is a chance under some scenarios that claims could reach very high levels. For example, under the model, there is a 10 percent chance that claims could exceed \$2.1 billion per year. While changes in the underlying input assumptions alter the results, the general character of the distribution survives extensive sensitivity tests.

The last result is intuitive. If a few large firms that have lots of underfunding fall into severe financial difficulty, a 'tail event' can occur. Similarly, if a bad economic scenario is encountered, underfunding and bankruptcy rates can escalate rapidly, causing a severe tail event.

In reality, we will pass through one particular economic scenario over the next 10 years and we have no idea which one it might be. Further, given this scenario, any number of bankruptcy combinations could arise, some of which cause few problems for the pension insurer and others that cause large losses. Many right-tail events in PIMS arise because either stock values or interest rates (or both) fall.

Systematic Risk

The relationship between interest rates and stock returns has an important effect on claims. In general, the worst simulated outcomes tend to occur in scenarios characterized by low stock returns or low interest rates. This is the "systematic risk" in pension insurance.

Idiosyncratic Risk

In addition to systematic risk, the program also faces idiosyncratic risk. This is the risk that some plan sponsors (or industries) that have lots of pension underfunding incur severe financial difficulty. It is possible for the agency to experience a run of claims, independent of market conditions.⁷ Some ‘tail events’ are attributable to this kind of risk, and some are attributable to both idiosyncratic financial difficulties of some large firms and overall unfavorable economic conditions. It turns out that about half of the variation in potential claims is explained by movements in stock returns and interest rates; the rest is attributable to idiosyncratic risk.

PBGC’s Financial Position

In order to generate the agency’s future financial position, we need to take into account its premiums, expenses, and investment returns.

Premiums in PIMS reflect a projected change in mortality table, together with the increase in the variable rate premium (VRP) interest rate to 100 percent of the 30-year Treasury bond rate, as provided by the Retirement Protection Act of 1994. For purposes of projections, we assume that flat-benefit plans with funding ratios above 90 percent (on a current liability basis) will set their ERISA full funding limits so that they do not pay the VRP. The flat rate premium of \$19 per participant is not indexed to inflation and, thus, its value gradually falls in real terms. Owing to the VRP component, premiums can vary substantially depending on market conditions. PBGC expenses in PIMS depend on the number and size of claims that arise in each simulation.⁸

Finally, the simulations assume that PBGC allocates one-third of its assets to equity securities and that it maintains a bond portfolio that immunizes its liabilities against interest rate risk.⁹

The mean outcome is an \$8.8 billion surplus in 2008 (in present value terms). However, the model also shows the potential for significant downside outcomes. In particular, there is nearly a 20 percent chance that the agency could return to a deficit in

⁷ The variance around these loss distributions is higher when equity returns are low.

⁸ Several PBGC actuaries have worked on the expense formula for PIMS. The result is a function of the existing level of liabilities, a natural depreciation of these costs over time (as each case moves through the process), and the number of new cases in the simulation.

⁹ The liabilities are immunized by purchasing sufficient amounts of zero-coupon Treasuries. We then pursue the goal of one-third equities in the portfolio. This ratio corresponds closely to the 33 percent share that characterized the PBGC portfolio as of yearend in fiscal year 1998. In the event that insufficient trust assets exist to reach one-third, we set the equity component to the maximum allowable limit. Any assets remaining after satisfying these two goals are invested in one-year Treasury bills.

the next 10 years and a 10 percent chance that the deficit could exceed \$6.3 billion in 2008. These outcomes are most likely if the economy performs poorly, in which case PBGC may experience both large claims and significant investment losses.

Concluding Remarks

The forecast methodology that PBGC used in prior years relied on a limited amount of information, primarily past claims experience. In effect, it assumed that the same economic conditions that prevailed in past years would repeat themselves and, further, that the frequency and size of claims experienced under these conditions also would be the same. PIMS recognizes the possibility that thousands of different paths of stock returns and interest rates could develop over future years and that many different claims sequences could occur within any given economic scenario. By quantifying a fuller range of uncertainty, the model helps PBGC assess its financial vulnerability from future events that may be significantly different than those that have characterized its history.

APPENDIX S

Single-Employer Data Tables

Table S-1

Net Financial Position of PBGC's Single-Employer Program (1980-1998)

Fiscal Year	Assets (in millions)	Liabilities (in millions)	Net Position (in millions)
1980	\$467	\$561	-\$95
1981	515	704	-189
1982	835	1,168	-333
1983	1,085	1,608	-523
1984	1,063	1,525	-462
1985	1,155	2,480	-1,325
1986	1,740	5,566 *	-3,826 *
1987	2,163	3,712	-1,549
1988	2,422	3,965	-1,543
1989	3,059	4,183	-1,124
1990	2,797	4,710	-1,913
1991	5,422	7,925	-2,503
1992	6,381	9,118	-2,737
1993	8,267	11,164	-2,897
1994	8,281	9,521	-1,240
1995	10,371	10,686	-315
1996	12,043	11,174	869
1997	15,314	11,833	3,481
1998	17,631	12,619	5,012

Source: PBGC Annual Report (1980-1998).

1986 values include \$1.8 billion in liabilities that were subsequently returned by a Supreme Court ruling to a reorganized LTV Corporation.

Due to rounding of individual items, rows may not add across.

This table was previously titled A-1 in Pension Insurance Data Book 1997.

Table S-2

PBGC Premium Revenue, Benefit Payments, and Expenses (1980-1998) Single-Employer Program

Fiscal Year	Total Premium Revenue (in millions)	Benefit Payments (in millions)	Administrative & Investment Expenses (in millions)	Premiums Minus Benefits Paid and Expenses (in millions)
1980	\$71	\$37	\$20	\$14
1981	75	57	21	-3
1982	80	94	24	-38
1983	82	137	27	-82
1984	81	169	30	-118

1998	826	208	313	208	21	9	2,198	847	216	263

Sources: PBGC Participant System (PRISM), fiscal year calculations, PBGC Management Reports, and PBGC Benefit Payment Reports.

Lump Sum payments include cash outs of pensions with de minimus present values and back payments to current pensioners.

Since some payees received both pensions and lump sum payments, total number of payees may be less than the sum of pensioners and lump sum recipients.

Excludes participants in probable termination status as of end of fiscal year.

Annual deferred payee totals have been adjusted to reflect subsequent improvements in data quality.

This table was previously titled A-2 in Pension Insurance Data Book 1997.

Table S-4

PBGC Payees and Benefit Payments by Industry (1998) Single-Employer Program

Industry	Payees		Benefit Payments		Mean Monthly Pension	Median Monthly Pension
AGRICULTURE, MINING, AND CONSTRUCTION	5,331	2.5%	\$20,798,654	2.5%	\$317	\$249

Due to rounding of individual items, values may not add up exactly across columns.

Claims figures shown in this table are calculated on a plan basis and identified with fiscal year of plan termination for each plan.

1975 termination and claims values are for 7/1/74 to 6/30/75. 1976 values are for 7/1/75 to 9/30/76. For 1977 on, values are for 10/1 of the prior calendar year to 9/30 of the current calendar year.

The annual numbers of trustee terminations shown in this table may differ from those reported elsewhere, as they reflect the fiscal year of plan termination, rather than the fiscal year in which the loss is recorded.

Values are subject to change as PBGC completes reviewing, establishes termination dates, and determines recoveries.

This table was previously titled A-9 in Pension Insurance Data Book 1997.

Table S-11

PBGC Single-Employer Claims (1975-1998)

Fiscal Year	Total Claims	Claims of Top 10 Firms and Percent of Total Annual Claims		Other Claims and Percent of Total Annual Claims

TOTAL (1975-1998)	\$6,027,390,530	\$3,168,667,773	52.6%	\$2,858,722,756	47.4%

Sources: PBGC Fiscal Year Closing File (9/30/98) and PBGC Case Administration System.

Due to rounding, percentages may not add up to 100 percent.

Claims figures in this table are calculated on a plan basis.

Annual claims for Top 10 firms are summations of all claims in that fiscal year associated with the Top 10 firms.

Values are subject to change as PBGC completes reviewing, establishes termination dates, and determines recoveries.

See Table S-12 for a list of the Top 10 firms with the largest value of claims.

This table was previously titled A-10 in Pension Insurance Data Book 1997.

Table S-12

Top 10 Firms Presenting Claims (1975-1998) Single-Employer Program

Top 10 Firms	Number of Plans	Fiscal Years of Plan Terminations	Claims (by firm)	Vested Participants	Average Claim Per Vested Participant	Percent of Total Claims (1975-1998)
1 Pan American Air	3	1991, 1992	\$776,745,843	37,472	\$20,729	12.9%
2 Eastern Air Lines	7	1991	552,730,569	51,182	10,799	9.2%

4 Sharon Steel	5	1994	232,192,487	6,886	33,720	3.9%
5 LTV Republic Steel	1	1986	221,920,051	8,208	27,037	3.7%
6 Kaiser Steel	4	1987, 1988	221,613,329	8,403	26,373	3.7%
7 CF&I Steel	1	1992	220,839,313	4,239	52,097	3.7%
8 Allis-Chalmers*	11	1985, 1986	185,735,060	9,055	20,512	3.1%
9 Uniroyal Plastics	1	1992	142,705,203	5,212	27,380	2.4%
10 Blaw-Knox	6	1992, 1994	118,950,890	5,659	21,020	2.0%
Top 10 Total	46		3,168,667,773	158,460	19,997	52.6%
All Other Total	2,609		2,858,722,756	468,983	6,096	47.4%
TOTAL (1975-1998)	2,655		\$6,027,390,530	627,443	\$9,606	100.0%

Sources: PBGC Fiscal Year Closing File (9/30/98), PBGC Case Administration System, and PBGC Participant System (PRISM).

Due to rounding, percentages may not add up to 100 percent.

Data in this table has been calculated on a firm basis and includes all plans of each firm.

* Does not include 1997 termination of plan sponsored by the reorganized Allis-Chalmers Corporation.

This table was previously titled B-2 in Pension Insurance Data Book 1997.

Table S-13

**PBGC Claims by Plan Funding Ratio at Termination (1975-1998)
Single-Employer Program**

Funding Ratio	Claims	
Under 25%	\$2,990,105,377	49.6%
25% - 49%	1,523,815,331	25.3%
50% - 74%	1,368,634,921	22.7%
75% and Over	144,834,901	2.4%
TOTAL	\$6,027,390,530	100.0%

Sources: PBGC Fiscal Year Closing File (9/30/98) and PBGC Case Administration System.

Calculations represent aggregated claims over the period 1975-1998.

Values and distributions are subject to change as PBGC completes reviewing, establishes termination dates and determines recoveries.

Funding ratios are calculated as the ratio of trust plan assets to plan benefit liabilities before recoveries from employers.

Due to rounding of individual items, percentages may not add up to 100 percent.

This table was previously titled A-11 in Pension Insurance Data Book 1997.

Table S-14

Average Claim per Vested Participant by Plan Size (1975-1998) Single-Employer Program

Number of Plan Participants	Vested Participants	Plans	Claims		Average Claim Per Participant	Claims (1998 Dollars)		Average Claim Per Participant (1998 Dollars)
Under 100	61,253	1,731	\$313,420,363	5.2%	\$5,117	\$437,085,069	5.3%	\$7,136

1995	37.28	31.39	33.37	—	14.56
1996	83.07	63.68	82.23	\$38.10	22.47
1997	—	—	51.57	28.70	20.73
1998	—	—	37.23	25.20	15.38

Definitions:

(A) Underfunding calculated from IRS Form 5500 filings.

(B) Data collected from companies in the preparation of the PBGC Top 50 list of largest underfunded plan sponsors.
Data for other firms is obtained from Standard & Poor's Compustat.

(C) Underfunding data from PBGC premium filings used to calculate the Variable Rate Premium.

(D) Data from filings made under Section 4010 of ERISA, which requires that companies annually provide PBGC with information on their underfunded plans, if the firm's aggregate underfunding exceeds \$50 million, or there is an outstanding lien for missed contributions exceeding \$1 million or an outstanding funding waiver of more than \$1 million.
Firms and plans included in the total may differ from year-to-year.

(E) Underfunding for plan sponsors with less than investment grade bond ratings.

This table was previously titled B-5 in Pension Insurance Data Book 1997.

Source: Internal Revenue Service Form 5500 Series Filings for single-employer plans with 100 or more participants.
 Due to rounding of individual items, totals may not exactly equal those in other tables or add up exactly across columns.
 Vested liabilities have been adjusted to an interest rate that, along with the GAM-83 mortality table, reflects the cost to purchase an annuity at the beginning of 1996.
 Funding data is reported by state of plan administration.
 *Less than \$500,000.
 This table was previously titled B-9 in Pension Insurance Data Book 1997.

 This table was previously titled B-10 in Pension Insurance Data Book 1997.

Table S-32

PBGC Maximum Guaranteed Benefits Single-Employer Program

Year of Plan Termination	Maximum Monthly Guarantee	Maximum Annual Guarantee
1988	\$1,909.09	\$22,909.08
1989	2,028.41	24,340.92
1990	2,164.77	25,977.24
1991	2,250.00	27,000.00
1992	2,352.27	28,227.24
1993	2,437.50	29,250.00
1994	2,556.82	30,681.84
1995	2,573.86	30,886.32
1996	2,642.05	31,704.60
1997	2,761.36	33,136.32
1998	2,880.68	34,568.16
1999	3,051.14	36,613.68

The Employee Retirement Income Security Act of 1974 (ERISA) mandates that the maximum guaranteed amount be adjusted annually based on changes in the Social Security contribution and benefit base.

The maximum guarantee applies to workers who retire at age 65 or later.

Maximum guarantees are reduced for retirees taking earlier retirement or electing survivor's benefits.

In some instances, where a pension plan has adequate resources or PBGC recovers sufficient amounts, a participant may receive benefits in excess of the maximum guarantee.

This table was previously titled B-11 in Pension Insurance Data Book 1997.

Table S-33

Premium Schedule of PBGC's Single-Employer Program

For Plan Years Beginning	Flat Rate Premium (per participant)	Variable Rate Premium
September 2, 1974 - December 31, 1977	\$1.00	—
January 1, 1978 - December 31, 1985	2.60	—
January 1, 1986 - December 31, 1987	8.50	—
January 1, 1988 - December 31, 1990	16.00	\$6 per \$1,000 of unfunded vested benefits (Maximum of \$34 per participant)
January 1, 1991 - June 30, 1994	19.00	\$9 per \$1,000 of unfunded vested benefits (Maximum of \$53 per participant)
July 1, 1994 - June 30, 1995	19.00	\$9 per \$1,000 of unfunded vested benefits (Maximum of \$53 per participant plus 20% of uncapped variable premium in excess of \$53 per participant)
July 1, 1995 - June 30, 1996	19.00	\$9 per \$1,000 of unfunded vested benefits participant plus 60% of uncapped variable premium in excess of \$53 per participant)
On or After July 1, 1996	19.00	\$9 per \$1,000 of unfunded vested benefits (No maximum)

This table was previously titled B-12 in Pension Insurance Data Book 1997.
